Part of the expansion of interest in the economics of education has reflected the development of extensive data on schools – partially as a result of movements to expand accountability of schools for performance. But a complementary impetus for this expansion has been the direct relationship between research and educational policy. The recent demands for 'evidence-based decision making' has heightened interest in the information about program effectiveness and the impacts of institutions on educational outcomes.

Outcomes

It is natural for economists to think in terms of a production model where certain factors and influences go in and products of interest come out. This model, called the 'production function' or 'input-output' approach, is the model behind much of the analysis in the economics of education. The measurable inputs are things like school resources, teacher quality, classroom peers, and family attributes, and the outcome is student achievement. Let us focus on the outcome,

first, and then move on to inputs, where more controversy has historically existed.

In the development of the field, the most frequently employed measure of schooling has been school attainment or simply years of schooling completed. The United States tradition led the world in investing in schooling. By the mid-1970s, three-quarters of US students completed high school, culminating a long national investment period that started with just 6% graduating from high school at the turn of the century. Many developed and developing countries, however, have recently mimicked this trend, as illustrated in **Figure 1**, which displays the increasing completion of secondary schooling for more recent age cohorts. By 2008, the growth in attainment around the world is readily seen.

The value of school attainment as a rough measure of individual skill has been verified by a wide variety of studies of labor market outcomes. In the United States, Mincer (1974) pioneered the approach that is now standard. Psacharopoulos and Patrinos (2004) have taken this analysis to the rest of the world, surpassing 100 countries for which estimates of the returns to years of schooling are available. The estimation considers the relationship between earnings (viewed as a direct measure of individual productivity) and schooling and labor market experience.

However, the difficulty with this common measure of outcomes is that it assumes a year of schooling produces the same amount of student achievement over time and in every country. This measure simply counts the time spent in schools without judging what happens in schools. Moreover, it neglects any complementary source of human capital development such as families, peers, or health inputs – thus, it does not provide a complete or accurate picture of outcomes. Today, more attention is focused on quality outcomes, and the most common measure is tests for cognitive skills (for a more general discussion, see Hanushek and Woessmann (2008)).

To the extent that the productive value of schooling largely involves the ability to make decisions under uncertainty and to adapt to new ideas and technologies (cf Nelson and Phelps, 1966; Welch, 1970), cognitive skills appear to be a valid measure of human capital. This conclusion is supported by recent studies that show a direct correlation between test scores and earnings in the labor market (Hanushek and Zhang, 2009).

While early studies of wage determination indicated relatively modest impacts of variations in cognitive ability after holding constant quantity of schooling, more recent direct investigations of cognitive achievement find generally larger labor market returns to measured individual differences in cognitive achievement. Three US studies provide very consistent estimates of the impact of test performance on earnings of young workers (Mulligan, 1999; Murnane et al., 2000; Lazear, 2003). These studies employ different nationally representative data sets that follow students after they leave school and enter the labor force. When scores are standardized, they suggest that one standard deviation increase in mathematics performance at the end of high schools translates into 10–15% higher annual earnings. In a different set of estimates using data on a sample of workers for the United States, Hanushek and Zhang (2009) provide estimates of returns of 20% per standard deviation. (The estimates for the United States do, however, exceed those for other countries.) One distinguishing feature of these estimates is that they come for a sample of workers throughout the career, as opposed to the prior estimates that all come from early-career earnings. Using yet another methodology that relies upon international test scores and immigrants into the United States, Hanushek and Woessmann (2012) obtain an estimate of 14% per standard deviation.

Even more significantly, society appears to gain in terms of productivity. Hanushek and Kimko (2000) demonstrate that quality differences in schools have a dramatic impact on

Figure 1 Secondary school completion rates, 2008. Source: Organisation for Economic Co-operation and Development, 2008. Education at a Glance 2008: OECD Indicators. OECD, Paris.

productivity and national growth rates. These estimates have been duplicated in a variety of studies (see Hanushek and Woessmann (2008)). Moreover, the implications of long-term growth and economic well-being of having different levels of achievement are truly astounding (Hanushek and Woessmann, 2011). There is also reason to believe that there is a causal relationship between cognitive skills and economic growth (Hanushek and Woessmann, 2012). These estimates of the impact of school quality on economic outcomes parallel the attention to quality and cognitive skills that has become a growing policy interest of many countries. As countries have approached more universal access to schooling, they have turned to issues of quality of publicly provided schooling.

Production

Let us now look at the other side of the education equation – the inputs, or determinants, of student achievement. Because outcomes cannot be changed by fiat, much attention has been directed at inputs – particularly those perceived to be relevant for policy such as school resources or aspects of teachers.

Analysis of the role of school resources in determining achievement begins with the 'Coleman Report,' the US government's monumental study on educational opportunity released in 1966 (Coleman et al., 1966). The report was conducted in compliance with a mandate of the Civil Rights Act of 1964 to investigate the extent of inequality in the nation's schools. Although this was not the first such effort, it was much larger and much more influential than any previous study. Only recently, with the now-common use of administrative databases on student performance compiled by states, have studies exceeded the survey information from the Coleman Report in breadth of samples and ability to investigate different educational circumstances.

The Coleman Report's greatest contribution was directing attention to the distribution of student performance – the outputs as opposed to the inputs. Instead of addressing questions of inequality by simply listing an inventory of differences of schools and teachers by race and region, it highlighted the relationship between inputs and outputs of schools.

Unfortunately, most of the attention the report generated focused on the report's conclusions rather than its innovative perspective. The controversial conclusion was that schools are not very important in determining student achievement; on the contrary, families and, to a lesser extent, peers are the primary determinants of performance variance. The findings immediately led to a large (but decentralized) research effort to compile additional evidence about input-output relationships in schools. (There were also extensive analyses of the report's methodology and of the validity of its inferences. See, for example, Bowles and Levin (1968), Cain and Watts (1970), and Hanushek and Kain (1972).) And, as discussed below, the common interpretations of the results of the Coleman Report are now recognized to be quite incorrect.

The underlying model that evolved as a result of this research is very straightforward. The output of the educational process – that is, the achievement of individual students – is directly related to a series of inputs. Some of these inputs – the characteristics of schools, teachers, curricula, and so forth – are directly controlled by policy makers. Other inputs – those of families and friends plus the innate endowments or learning capacities of the students – are generally not controlled. Further, while achievement may be measured at discrete points in time, the educational process is cumulative; inputs applied sometime in the past affect students' current levels of achievement.

Family background is usually characterized by such sociodemographic characteristics as parental education, income, and family size. Peer inputs, when included, are typically totals of a student population's sociodemographic characteristics for a school or classroom. School inputs include teacher background (education level, experience, sex, race, and so forth), school organization (class sizes, facilities, administrative expenditures, and so forth), and district or community factors (e.g., average expenditure levels). As discussed elsewhere, one set of analytical problems flows from the lack of measurement of innate abilities of individuals and the imprecise measurement of the history of educational inputs (Hanushek, 1979, 1986). A second set of concerns that has received extensive recent attention relates to applying causal interpretations to the estimates. Both are discussed below.

In many ways, the analysis of educational production breaks into two distinct periods. The first – running from the Coleman Report in the mid-1960s through the mid-1990s – largely relied upon relatively small and specialized data sets that contained information on student outcomes and on some set of measures of school resources. The second period – running from the mid-1990s until now – largely moved to administrative databases with longitudinal information on student achievement for entire states over time. It took the results of the early period research that indicated no consistent relationship between measured school inputs and outcomes as a starting point (see the next section) and turned to intensive investigations of teacher quality and other specific aspects of schools.

The Importance of Measured School Inputs

The state of knowledge about the impacts of resources is best summarized by reviews of available empirical studies. Most traditional analyses of education production functions directed their attention at a relatively small set of resource measures, and this makes it easy to summarize the results (Hanushek, 2003).

Table 1 provides a tabulation of estimates of the impact of school inputs for studies that appeared before 1995. (Such reviews of empirical studies appeared first in 1981 (Hanushek, 1981) and were updated over time with additional studies. With stable results to the overall pattern of findings, there has been no subsequent updating of research past 1995, and the general pattern of results has become widely accepted.) The 90 individual publications for this analysis contain 377 separate production function estimates and form the basis of the conclusions about the impacts of measured inputs. The table indicates the sign of the estimated impact of a given resource on student performance; positive estimates imply that more resources are associated with

Table 1 Percentage distribution of estimated effect of key resources on student performance, based on 377 studies available through 1995

Resources	Number of estimates	Statistically significant		Statistically insignificant
		Positive	Negative	
Real classroom resources				
Teacher-pupil ratio	277	14%	14%	72%
Teacher education	171	9	5	86
Teacher experience	207	29	5	66
Financial aggregates				
Teacher salary	119	20%	7%	25%
Expenditure per pupil	163	27	7	34
Other				
Facilities	91	9	5	86
Administration	75	12	5	83
Teacher test scores	41	37	10	53

Source: Hanushek, Eric, A., Summer, 1997. Assessing the effects of school resources on student performance: an update. Educational Evaluation and Policy Analysis 19 (2), 141–164, revised.

higher student outcomes and the opposite for negative estimates. Additionally, information is provided about statistical significance or our confidence that there is a real effect of the resources.

For classroom resources, only 9% of studies on teacher education and 14% of studies on teacher-pupil ratios found a positive and statistically significant relationship between these factors and student performance. (This summary concentrates on the results. Details of the underlying analyses and of the selection of studies for this tabulation are found in Hanushek (1986, 1997). The first column provides a count of the total number of estimates addressing the impact of the given resource.) Moreover, these studies were offset by another set of studies that found a similarly negative correlation between those inputs and student achievement. Twenty-nine percent of the studies found a positive correlation between teacher experience and student performance; however, 71% still provided no support for increasing teacher experience (being either negative or statistically insignificant).

Studies on the effect of financial resources provide a similar picture. There is very weak support for the notion that simply providing higher teacher salaries or greater overall spending will lead to improved student performance. Per pupil expenditure has received the most attention, but only 27% of studies showed a positive and significant effect. In fact, 7% even suggested that adding resources would harm student achievement. It is also important to note that studies involving pupil spending have tended to be the lowest-quality studies, and thus there is substantial reason to believe that even the 27% figure overstates the true effect of added expenditure (Hanushek et al., 1996; Hanushek, 2003).

While the general conclusions about the inconsistent impacts of school resources were intensely debated through the 1980s and 1990s, the general conclusions have now been broadly accepted, and the research has moved to other areas. (Some idea about the debates can be seen in the various chapters in Burtless (1996). The controversy did continue with more specific debates about the effects of class size reduction, see Hanushek (1999), Krueger (1999), and Mishel and Rothstein (2002), although that too has largely disappeared.) Specifically, both the research and policy discussion now recognizes that 'how' resources are used is generally much more important than simply 'how much' is available.

On the research side, as suggested, the previous discussions do not distinguish among studies on the basis of any quality differences, so the results could be distorted by not adjusting the tabulations. While 'study quality' has a variety of subjective components, the available estimates can be separated by a few objective components of quality. First, while education is cumulative, frequently only current input measures are available, which results in analytical errors. Second, schools operate within a policy environment set almost always at higher levels of government. These reasons, combined with large panel data sets on student outcomes that come from state accountability data have led almost all studies in the second phase of research to focus on gains in student learning over time and on samples of individual students and classrooms rather than aggregate data on schools, districts, or states. (While these issues of estimation had been known for a considerable time (see Hanushek (1979)), the broad empirical application did not come until administrative databases became more readily available.)

There has also been a proliferation across the globe of studies of educational performance. One surprising result has been that many of the conclusions hold equally for developing countries, where resource constraints would seem to be much more important (Hanushek, 1995; Glewwe et al., 2013). Moreover, there has been a move toward using more evidence in policy decisions, led in part by the international assessments of evidence by John Hattie (2009).

Do Teachers and Schools Matter?

Because of the Coleman Report and subsequent studies discussed above, many people tended to argue that schools do not matter and that only families and peers affect performance. Unfortunately, these interpretations have confused measurability with true effects.

Extensive research over the past 45 years has made it clear that teachers do indeed matter. The simple definition of teacher quality used here, as first developed in Hanushek (1971), is an output-based measure. In this work, teacher effectiveness is assessed directly from student performance, instead of the more typical input measures based on characteristics of the teacher and school. High-quality teachers are ones who consistently obtain higher than expected gains in student performance, while low-quality teachers are ones who consistently obtain lower than expected gains. (In statistical terms these estimates employ covariance models, where fixed effects are estimated for individual teachers.) When this approach has been used, large variations in performance have been uncovered.

In fact, the degree to which teacher differences affect performance is impressive. Looking at the range of quality for teachers within a single large urban district, teachers near the top of the quality distribution can get an entire year's worth of additional learning out of their students, compared to those near the bottom (Hanushek, 1992). In subsequent work,

Rivkin et al. (2005) provide another estimate of the importance of teachers: having a good teacher instead of an average teacher for 3–5 years in a row can lead to achievement gains that equal the average difference in achievement of a student from a poor family as opposed to a better off family.

This work, now commonly called 'value-added analysis' because of the focus on what individual teachers contribute to student learning, has produced quite consistent estimates of how much variation there is in the impact of teachers (Hanushek and Rivkin, 2010). And, it has become one of the largest and most vibrant areas of educational research. Numerous recent investigations of teacher quality have focused on issues such as the best statistical approaches to employ and the interpretation of estimated differences across classrooms when students might not be randomly assigned to individual teachers. (For a discussion of these issues and the competing views, see Hanushek and Rivkin (2012).)

Part of the interest in these estimation issues has been raised by the application of estimates of teacher value added to policy. For example, in 2011, the Los Angeles Times newspaper published value-added ratings for individual teachers (Song and Felch, 2011), and this was followed by similar publications in New York City and elsewhere. Additionally, the teachers in the Washington, DC, schools have been partially evaluated on the basis of such value-added calculations (Isenberg and Hock, 2010). Moreover, early evidence suggests that use of these teacher evaluations has a positive impact on student outcomes (Dee and Wyckoff, 2013). These discussions have elevated the research attention to estimating the impacts of teachers and principals. (Investigations of principals are more difficult from a statistical viewpoint and have only recently been developed; see Branch et al. (2012).)

Based on existing value-added measures, the economic impact of teacher quality appears to be very large. **Figure 2** provides estimates that combine information about the impact on achievement of teachers at different points in the quality distribution with estimates of the impact of achievement on a student's future income (Hanushek, 2011). The figure plots the gains (or losses) in future income from a class of students having a high- (low-) quality teacher, all compared to an average teacher. Class size directly affects these estimates because a given teacher has a greater impact on outcomes when there are more students in the class. From this figure, a teacher at the 75th percentile of the quality distribution with a class of 25 students produces over $300 000 more future income compared with an average teacher. A teacher at the 25th percentile produces a similar loss compared to the average teacher.

These estimates, produced from combining the results of many existing studies, have been confirmed by an innovative study that links student outcomes for individual teachers with their actual labor market earnings observed through tax records (Chetty et al., 2014). They find individual teachers in the bottom 5% can reduce lifetime earnings of their students each year that they teach by over $250 000.

Efficiency

Efficiency involves the relationship between inputs and outputs in a production process. The underlying notion is that production is efficient if given inputs produce the maximum output. The simplicity of this statement, however, obscures a variety of complexities that arise when the concept is actually applied.

Typically economics does not devote much attention to the analysis of efficiency. If there are competitive markets, the behavior of producers and consumers tends to drive outcomes toward efficient production. Because of this basic theorem, it is common simply to assume efficiency.

In education, however, efficiency is never a given. First, education is generally publicly provided. Governmental organizations, which do not face the same incentives as private firms, cannot be expected to move toward efficient production. In particular, few school personnel are rewarded

Figure 2 Impact on student lifetime incomes by class size and teacher effectiveness (compared to average teacher).

or punished based on the outcomes students obtain, making the incentives for performance minimal or nonexistent. Second, it is difficult to find information on school efficiency. With complete information, parents might be expected to pressure schools to use resources – either through local political processes or through moving to districts that did better (Tiebout, 1956). Because student performance is influenced by factors schools cannot control – i.e., input from family and friends – simply observing student achievement does not accurately reflect school contribution. Thus, parental and voter pressures on schools are lessened by imperfect information.

The underlying political economy of schools that can preserve such apparently large inefficiencies in resource use deserves considerably more research.

Competition and Incentives

The lack of direct incentives within schools has led to investigations of circumstances where incentive forces may be stronger. While there have been a wide variety of proposed changes (e.g., Hanushek et al. (1994)), most have not been implemented or analyzed sufficiently to draw any conclusions about their efficacy.

The classic argument for competition comes from Friedman (1962) with his arguments for vouchers. The well-known arguments suggest that separating the finance of schooling from the production of schooling by allowing students to choose the school they attend would improve individual satisfaction with the outcomes (Nechyba, 2006). Within the United States, this approach has been vigorously debated, but few examples of implementation have occurred. The most celebrated application has been Milwaukee, Wisconsin, where vouchers have been available to a (constrained) number of poor children since 1990 (Rouse, 1998; Carnoy et al., 2006), but they have also been available in Cleveland, Washington, DC, and elsewhere (Wolf et al., 2010). A number of privately financed alternatives have also been offered (Howell and Peterson, 2002). Most of the attention to these voucher programs has centered on the student outcomes of students in them as compared to public schools. (A variety of controversies has developed in these analyses. Perhaps the primary analytical issue is dealing with selection of students and an appropriate comparison group. See, for example, the discussions in Witte (1999), Rouse (1998), and Greene et al. (1998).) Because these programs have been very marginal to the education system, there has been little suggestion that the public schools have made any adjustments in response. Thus, these choice experiences have not provided information about how public schools might react to a larger, more institutionalized program.

Private schools offer one possibility for better understanding the effects of competition. They must compete with the public schools in order to attract clients and thus they are subject to stronger pressures to provide high levels of performance. The literature on Catholic school performance is summarized in the articles by Neal (1997) and Grogger and Neal (2000). The evidence has generally indicated that Catholic schools on average outperform public. This superiority seems clearest in urban settings, where disadvantaged students face fewer options than others. This evidence is, nonetheless, subject to some caveats. First, as recognized since some of the earliest work on the topic (Coleman et al., 1982), it is difficult to separate performance of the private schools from pure selection phenomena. Specifically, since private school students could have attended public schools but instead pay extra for private schooling, they are clearly different than the public school students with identical measured characteristics. A variety of alternative approaches has been taken to deal with the selection problem, and a rough summary of the results after those efforts is that there remains a small advantage from attending Catholic schools. (Grogger and Neal (2000) suggest, however, that there is no advantage to attending private elite schools – a surprising result given the extra cost generally involved in that. These results are possibly due to selection problems, but it is not a simple relationship because most people would expect positive selection into these elite schools.) Second, this literature says little about the distribution of school quality within the Catholic sector.

Within the public sector, it is widely believed that school quality varies considerably across schools, and one might suspect that the same holds true for private schools.

One important potential element competition comes from other public school jurisdictions. Specifically, households can choose the specific jurisdiction and school district, in the manner of Tiebout (1956), by their choice of residential location. While adjustment is costly, these choices permit individuals to seek high-quality schools if they wish (Epple and Nechyba, 2004). Residential location decisions are of course complicated, involving job locations, availability of various kinds of housing, school costs and quality, and availability of other governmental services. Given choice opportunities plus voting responses, this model suggests pressure on schools to use resources effectively. Otherwise one might expect housing values to be affected.

The simple choice model would suggest naturally that larger numbers of schools or school districts per student would offer more opportunities for residents and thus more competition across schools. This simple model motivates the empirical analyses of Borland and Howsen (1992) and its extension and refinement in Hoxby (2000) and in Hanushek and Rivkin (2003). The simple inclusion of measures of concentration indicates that areas with less choice have poorer schools on average (Borland and Howsen, 1992). Hoxby (2000) pursues alternative strategies to look at the causal impact of concentrations and finds a larger estimated impact of competition on the performance of schools, although the robustness of her conclusions has been challenged by Rothstein (2007). Hanushek and Rivkin (2003), pursuing an alternative strategy, find competitive impacts on performance of urban schools and that these are particularly important for low-income students who have fewer mobility options.

In the United States, the rise of charter schools has provided an additional element of choice. Charter schools are public schools that have the freedom to be subject to less regulation and to offer different programs from the traditional public schools. They are schools of choice and do not charge any tuition fee. In 2011, there were over 5000 charter schools in the

United States, serving 3.6% of the school population (U.S. Department of Education, 2013: Table 117). The analysis of their performance shows considerable variation in effectiveness – ranging from much better than corresponding public schools to much worse (see, e.g., Hanushek et al. (2007), CREDO (2009, 2010, 2013), Abdulkadiroğlu et al. (2011)).

Finance of Schools

Public finance economists have devoted considerable energy to the study of the finance of schools, largely from the viewpoint of traditional tax and expenditure policy. The educational policy component of this involves equity in the provision of education. These considerations are largely motivated by the many studies that show wide disparities in achievement by race and socioeconomic background (e.g., Coleman et al. (1966), Hanushek (2001)). Nonetheless, the typical discussion of equity concentrates primarily on spending disparities across schools and districts, even in the face of evidence suggesting that student outcomes are not closely related to spending and resources (Hanushek, 2003).

Indeed, one of the most significant policy issues of the past 30 years in the United States has been the appropriate way for states to fund local schools (Fischel, 2006). While most states have employed a compensatory aid formula to ameliorate some local governments' difficulty in raising taxes, these measures have only partially solved the problem. The issue became the subject of court action in the 1960s, with the case of Serrano versus Priest in California. Suits in many other states followed (Hanushek and Lindseth, 2009). As a result, some significant narrowing of spending variations occurred (Murray et al., 1998).

However, there has been surprisingly little analysis of the impacts of these suits. This is important to undertake, because the prior research discussed above does not show a clear link between increased funding and school quality or student performance. From the perspective of educational outcomes, then, the value of spending changes related to equalization court cases and the related legislative actions remain an open question (Hanushek, 1991; Hanushek and Lindseth, 2009). To date, little research has focused on the achievement impacts of school finance policies and those that have looked at outcomes have not found much impact (e.g., Downes (1992), Cullen and Loeb (2004), Greene and Trivitt (2008)). Hanushek and Lindseth (2009) investigate the achievement impact of major court decisions in Kentucky, Massachusetts, New Jersey, and Wyoming. With the possible exception of Massachusetts, there is little evidence of any impact of major court spending decisions on student achievement. A broader, nation-wide analysis of district spending on earnings outcomes also found no beneficial relationship between the two, except perhaps for Black females (Hanushek and Somers, 2001).

Some Conclusions and Implications

The existing research suggests inefficiency in the provision of schooling. It does not indicate that schools do not matter. Nor does it indicate that money and resources never affect achievement. The accumulated research simply says there is no clear, systematic relationship between resources and student outcomes.

The persistence of this raises important questions about current education policy, as well as a real need for further research.

The main conclusion of this research is that policy decisions should not focus on school resources, because the impact of resources on student achievement is unknown at this time. The policy solution seems to be to establish incentives – rewards or consequences related to student outcomes – and then to permit local schools to develop their own game plans for meeting these goals. While a wide variety of incentives have been proposed – such as vouchers, merit pay, or contracting out – most have not been implemented or analyzed sufficiently to determine their efficacy.

A final major issue raised by these analyses is their implication for other kinds of studies (Hanushek, 1996). Most studies involving human capital are interested in its effect on other aspects of behavior. For these studies schooling is largely tangential to other interests, and researchers are typically simply looking for an easy and readily available measure of school quality. The most common has been spending per pupil. However, the inefficient production of human capital introduces natural measurement problems. Direct spending is no longer a good measure of quality because it has no perceivable bearing on performance. Second, it is well known that families have considerable influence on student achievement, implying that school resources are only part of the equation. Both factors suggest studies that measuring student achievement just through resource investment has a high potential for distortion.

Education for the Gifted and Talented

David W Chan, The Chinese University of Hong Kong, Hong Kong, People's Republic of China

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gifted and talented children and youth, because of their precocity, intensity, and complexity, require differentiation in curriculum and teaching to enable them to develop to their full potential. They need and benefit from accelerated and enriched learning experiences commensurate with their levels of giftedness and talent. Such gifted programming can be represented by program models that focus on academic talents and acceleration (e.g., Talent Search Model), and those that focus on creative productivity and enrichment (e.g., Schoolwide Enrichment Model). Gifted learners may also experience social and personal issues that require support and counseling attention from teachers and parents.

Giftedness and Talent

'Gifted' vs 'Talented'

Education for the gifted and talented is commonly referred to as gifted education and/or talent development. The terms 'gifted' and 'talented' are almost always used synonymously to describe children and youth functioning with superior cognitive abilities and performing at levels far above what is typical for their chronological age. Used interchangeably, a child can be described as 'verbally gifted' and 'mathematically gifted' or 'verbally talented' and 'mathematically talented.' Some researchers and practitioners however have made a distinction. They refer 'gifted' children to those children with generally broad and high abilities across different domains (e.g., intellectually gifted or creatively gifted), and 'talented' children to those children with special abilities in specific domains (e.g., artistic talent as in musically talented). Others describe children as 'gifted' when referring to academic disciplines or domains, and 'talented' when referring to nonacademic domains. Still others see talent and giftedness on a continuum specifying levels of giftedness, with giftedness at the upper or high end. Perhaps, the most salient distinction is made by Francoys Gagne, who defines 'gifts' as untrained natural abilities or natural aptitudes, and 'talents' as learned capabilities or specific skills in his Differentiated Model of Giftedness and Talent. In general, there are no solid empirical grounds for making the distinction other than common usage, and the terms are best interpreted as interchangeable.

Defining Giftedness

Regardless of whether one distinguishes between 'gifted' and 'talented,' 'giftedness' as a construct has been defined in many different ways throughout its history (see Sternberg and Davidson, 2005). Lewis Terman is probably one of the first to define giftedness in terms of high IQ. In his longitudinal study of the physical, psychological, social, and professional development of 1528 gifted children with IQs averaging 151, his inclusion criterion was an IQ above 135. Since Terman's time, researchers and practitioners have developed a consensus that giftedness is often not captured by a single unidimensional IQ score. For example, the 1972 US Office of Education Report (Marland Report) defined giftedness as superiority in six categories that include general intellectual ability, specific academic aptitude, creative or productive thinking, leadership ability, visual and performing arts, and psychomotor ability. In subsequent revisions, psychomotor ability was left out, but the view that high IQ is but one aspect of giftedness remains the clear message. A similar view could be discerned in Joseph Renzulli's (1978) three-ring model, where giftedness is defined by the confluence of high-task commitment and high creativity in addition to above-average ability.

From a slightly different perspective, other researchers and practitioners have broadened giftedness to correspond to the changes in the conception of intelligence as multidimensional. For example, Howard Gardner redefined intelligence and proposed multiple intelligences that can characterize gifted individuals, suggesting that each individual may excel or be gifted in one or more intelligences. His multiple intelligences include verbal-linguistic, logical-mathematical, visual-spatial, musical, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist intelligences. Emphasizing cognitive processes rather than content domains, Robert Sternberg (1985) proposed three major kinds of intelligence or triarchic abilities that include analytic (academic), synthetic (creative), and practical (applied) abilities, thus reflecting three major kinds of giftedness. Nonetheless, irrespective of how giftedness is conceptualized, the adoption of a particular definition of giftedness has specific implications for educators in their identification of gifted learners for talent recognition and development.

Education for the Gifted and Talent Development

Despite the diversity in giftedness theorizing, educators in gifted education generally conceptualize giftedness simply as unusually high ability in any area, including high global IQ as well as domain-specific ability. Given the multiple manifestations of giftedness, they tend to strive to be inclusive in identifying gifted and talented children and youth through the adoption of clearly defined but broad conceptions of giftedness and the use of multiple alternative criteria with assessment over time. It is also understood that giftedness may appear in different forms in different ethnic or socioeconomic groups and in different cultural settings. Partly because of the variability in the conceptions of giftedness and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92137-8

the diversity in the identification procedures and partly because of the equity issue in educational provisions, some researchers and practitioners have called for the shifting of the focus of gifted education to talent development. Accordingly, talent development emphasizes developing the talents, gifts, and capabilities of all students, including highly able or high-end learners. Thus, instead of asking whether a child is gifted or talented, the question becomes one of asking how gifted or talented the child is, and how one could help to bring forth the giftedness or talent in the child. Parenthetically, this orientation also eliminates the awkwardness of calling some children 'gifted' and others 'ungifted,' 'nongifted,' or 'not gifted.'

Differentiation in Gifted Education and Talent Development

For educators with a talent development focus, gifted education is very similar to quality education that emphasizes addressing the specific learning needs of individual students, including gifted learners, while allowing students to explore and master high-quality curriculum as well as developing their potentials and talents. For educators with a focus on educating gifted learners, gifted education implies differentiation or adapting curriculum and instruction for gifted learners who are characterized by their capacity to learn faster, remember more, find and solve problems more readily, manipulate abstract ideas and make connections more readily, process information more effectively, and generate more new and unusual ideas than their age peers. Although the concept of differentiation has been more recently used to denote teaching a range of diverse learners, including but not limited to gifted learners, with emphasis on the general education setting, differentiation in the context of gifted education is useful for considerations in areas of meeting gifted learners' needs and characteristics, adapting curriculum and instruction, and teacher training and education.

Characteristics of Gifted Learners

Understanding the specific characteristics and needs of gifted learners could be considered the prelude to efforts of differentiation, and these specific needs and characteristics provide grounds on justification for ability grouping of gifted learners. In this regard, Joyce VanTassel-Baska and Tamra Stambaugh (2006) named three characteristics as most relevant for gifted and talented curriculum planning. They are precocity, intensity, and complexity. Precocity is often the key characteristics, as gifted learners admitted to gifted programs are often at least 2 years ahead in their talented (e.g., language and mathematics) areas, and are powerfully motivated to learn fast. Intensity may be manifested affectively in gifted learners' emotional responsiveness or sensitivity. Equally and even more relevant for learning are the cognitive manifestations in gifted learners' capacity to focus and concentrate for long periods of time on an idea or a subject that fascinates them. Ellen Winner (1996) called this characteristic 'a rage to master' to emphasize the passion and strong motivation of gifted learners. Complexity refers to gifted learners' capacity to engage in abstract or higher level thinking at a young age. It also refers to their preference for challenges and hard work above their current levels of functioning. Winner called this characteristic "an insistence on marching to their own drummer" to include gifted learners' autonomy and preference for independent work. Perhaps, a fourth characteristic of asynchrony or asynchronous development initiated by the Columbus Group could be added, referring to the uneven intellectual development of gifted learners or the discrepancy engendered by their advanced cognitive abilities and heightened emotional sensitivity (see Silverman, 1997). This characteristic highlights that affective needs of gifted learners must also be addressed in differentiation efforts, as gifted learners could be more vulnerable to negative perfectionism, underachievement, and problems in peer relationships.

Curriculum Dimensions

Curriculum differentiation for gifted learners is best exemplified by Joyce VanTassel-Baska's Integrated Curriculum Model that defines three curriculum dimensions for differentiation (see VanTassel-Baska and Stambaugh, 2006). The three dimensions are content, process and product, and concept. In the content dimension for gifted learners, content acceleration dominates. Students are encouraged to move rapidly at a rate commensurate with their capacity through the content area that could be highly sequential and cumulative, mastering skills and concepts within the predetermined domain of inquiry. Mastery learning time is conserved by testing for proficiency, assigning advanced work, and reorganizing basic skill areas into high-level skill clusters. In this manner, content acceleration promotes more efficient and challenging learning experiences for gifted learners.

In the dimension of process and product for gifted learners, the emphasis is on learning scientific and social investigatory skills with the development of a high-quality product. The instruction pattern is dominated by consultation and independent work. The focus is on higher level thinking, critical and creative thinking, problem finding and problem solving, and research skills that allow students to learn to think independently of textbooks and known resource materials. Unlike the topics of inquiry in the content dimension, the selected topics for exploration are determined by student interest, and the content is incidental. Evaluation is product-based instead of proficiency-based, and the emphasis is on in-depth study of selected topics rather than fast-paced surveying of the domain of inquiry. Thus, differentiation in this dimension allows gifted learners to engage in the process of constructing knowledge for themselves.

Unlike the two dimensions that are based on subject matter or process skills, the concept dimension is organized by key ideas, themes, and principles within and across domains of knowledge. The instructional context is highly interactive, and students are engaged in reading, reflecting, and writing in response to the interpretive issues raised for discussion, debate, and interdisciplinary thinking. Gifted learners are evaluated on their high-level aesthetic appreciation of powerful ideas and insight in essays or artistic products that show evidence of integrating or synthesizing forms and meaning across areas of study. Differentiation in this dimension allows gifted learners

to be exposed to many ideas and provides them with an intellectual framework not available in studying only one content area.

Teachers of Gifted Learners and Teacher Education

In a study of talent development of 120 individuals who had attained eminence in their fields by the age of 40, Benjamin Bloom (1985) found that different types of teachers were needed at different stages of the individuals' development. Specifically, the student successively needed a teacher who would teach the basics and the joy of learning, a teacher who would individualize learning with an emphasis on skills and self-discipline, and a master teacher who could raise the student to the level of an expert. Thus, teachers of gifted learners not only need the knowledge, skills, and dispositions to facilitate high-level learning, they also need to know how to differentiate to challenge gifted learners and provide opportunity to allow students to make continuous progress in developing their potential.

Laurie Croft (2003), in reviewing studies on teachers of the gifted, suggested that while these teachers share with effective teachers in general education certain common characteristics such as spontaneity, acceptance, creativity, and self-realization, they also have to develop areas of expertise that teachers of general education do not require. Based on a systematic review of past studies on teacher characteristics and competencies, John Feldhusen (1997) observed that the characteristics found in successful teachers of gifted learners were similar to those found in gifted and talented students, and were desirable in all teachers. These characteristics include being highly intelligent, achievement oriented, knowledgeable, and flexible; having cultural and intellectual interests; respecting individual differences; and relating well with gifted individuals. Feldhusen also summarized the competencies of successful teachers of gifted learners. These competencies include skills in teaching thinking skills, problem solving, and creativity; in interacting with students; in using appropriate motivational techniques; in conducting student-directed activities; and in facilitating independent research. In addition, Feldhusen also cautioned that competencies could be domain-specific in that competencies required in teaching certain specific content domains such as science and mathematics could be very different from those required for teaching other domains such as art and music. Thus, comprehensive and effective preparation opportunities in teacher education need to be developed to help dedicated teachers transform their successful characteristics and competencies into gifted education practice.

In 2006, the Initial Knowledge and Skill Standards for Gifted and Talented Education developed jointly by two US national organizations, the Council for Exceptional Children and the National Association for Gifted Children, were approved as national official standards to guide the development of programs to prepare educators of gifted learners. The 10 standards are foundations, development and characteristics of learners, individual learning differences, instructional strategies, learning environments and social interactions, language and communication, instructional planning, assessment, professional and ethical practice, and collaboration. These standards can be vehicles to facilitate the integration of gifted education into teacher preparation programs at various levels in the US as well as around the world.

Developing Gifted Programs or Programs for Talent Development

Acceleration and Enrichment

Acceleration and enrichment are terms that are commonly used in gifted education to describe types of programs differentiated for gifted learners. These program types generally have different strategies for organizing curriculum and arrangements for grouping gifted learners.

Acceleration is seen as moving faster through grade-level or subject matter curriculum than same-age peers, including offering standard curriculum to gifted learners at a younger-than-usual age. It can be viewed as adaptation involving mainly the curriculum dimension of content. Enrichment is seen as extending, supplementing, and going beyond the regular curriculum in greater depth or breadth and thus providing richer and more varied educational experiences to gifted learners. It can be viewed as adaptation involving mainly the curriculum dimension of process and product. Research studies on acceleration and enrichment have indicated that both accelerated and enriched classes result in higher achievement for gifted learners. For example, in his Michigan meta-analysis studies, Kulik (2003) reported that the accelerates outperformed the non-accelerates by about 1 year, and students in enriched classes outperformed other students by about 4 months.

On closer examination, the distinction between acceleration and enrichment however easily breaks down. Any enrichment experience will generally involve new topics or greater depth and are advanced or accelerated when compared with the regular curriculum. Similarly, acceleration with advanced subject matter generally involved enriched experiences. One way to distinguish the two by educators is to include as acceleration any strategy that results in advanced placement or credit and to include as enrichment any strategy that supplements or goes beyond standard grade-level work without advanced placement or credit. It is believed that well-round, coherent, and long-range gifted programs should provide both enrichment and acceleration opportunities for gifted learners.

Two Exemplary Program Models

To plan and conduct learning activities for gifted learners, one needs a viable program model. Joyce VanTassel-Baska (2000) specified that a viable model should provide a system for designing and developing appropriate curriculum for the target population of gifted learners. In addition, the model should differentiate according to the principles of gifted education, applicable to all major content areas of school-based learning, and to different age and grade levels. In past decades, numerous viable program models have emerged, with different emphases on acceleration and enrichment. Two exemplary program models, the Talent Search Model and the Schoolwide Enrichment Model, representing respectively the different emphasis on acceleration and enrichment are introduced here. Both models have enjoyed widespread use and research attention,

and have years of research, development, and implementation behind them.

The Talent Search Model

Talent search was pioneered by Julian C. Stanley at Johns Hopkins University in 1972 in his Study of Mathematically Precocious Youth (SMPY). It has evolved and expanded in many ways, and can be viewed not only as a curriculum model but also a program model of overall talent development with an emphasis on acceleration options. Broadly conceptualized, it is a model for the discovery and development of academic talent and its overall purpose is to educate for individual development over the lifespan (Lupkowski-Shoplik et al., 2003). Two steps are involved in the discovery of students who are exceptionally able academically. The first step is the identification of students who have demonstrated a high level of academic performance, as documented by high performance on grade-level tests (e.g., 97th percentile). The second step is to determine these students' potential for academic challenge by out-of-level testing or testing them with tests above their grade levels (usually 2 years).

Initially, the interest in SMPY was in finding adolescents (mainly seven-grade and some eight-grade students) who were exceptionally gifted in mathematics, so the mathematics section of the Scholastic Aptitude Test (SAT-M) was used as a measure of students' mathematical reasoning abilities. Students who scored at or above 51st percentile for male college-bound high school seniors were considered mathematically precocious. Starting from 1980, talent search was extended to verbally gifted youth, and the Verbal section of the SAT (SAT-V) was used to identify them. After the revision and renaming of the SAT as the Scholastic Assessment Test (SAT I), the SAT continues to serve as the testing instrument that taps into high-level verbal and mathematical reasoning to identify students. In addition to the SAT I, another college entrance exam, the American College Testing Program is also used.

The identification of students as mentioned above with the use of a secure and difficult testing instrument to tap into high-level verbal, mathematical, and spatial reasoning is followed by the diagnostic testing–prescriptive instructional (DT-PI) approach. These identified students are then counseled and encouraged to pursue any of a 'smorgasbord' of acceleration options that include attending college part time or earning college credit by examination, skipping a grade, receiving individual highly accelerated tutoring, or entering college early. Thus, the DT-PI approach provides identified students with different forms of educational facilitation through utilizing acceleration or curricular flexibility and by developing fast-paced academic programs for these students.

Research studies have been conducted to demonstrate the viability of the Talent Search Model, suggesting positive results of accelerative practices and a lack of negative consequences such as knowledge gaps or loss of interest. It has been concluded that intellectually gifted students as accelerates consistently outperformed the non-accelerates, and they would not achieve as highly if talent search educational opportunities were not provided for them. Benefits for talent search participants also included improved zest for learning, enhanced self-esteem, better education preparation, and early entrance to college and a profession. Of particular values were the experiences of intellectual stimulation, the acknowledgment of talents, and the contact with intellectual peers, as evaluated by talent search participants. Currently, a 50-year longitudinal study (1972–2022) is ongoing with a sample of 6000 talent search participants.

Over the years, the Talent Search Model has been adopted in different regional centers in the US, extending from identifying academically talented students at the junior high level to those of the elementary level. With its successful application in the US, the Talent Search Model has its influence in the development of variations of the model in East Asian countries or regions such as Mainland China and Taiwan.

The Schoolwide Enrichment Model

The School Enrichment Model (SEM) was developed in the mid-1970s by Joseph Renzulli of the University of Connecticut and was implemented as a gifted and talented programming model in school districts in Connecticut (Renzulli and Reis, 2003). It combines two previously developed models, the Enrichment Triad Model (ETM) and the Revolving Door Identification Model (RDIM). Like the Talent Search Model, the SEM is more than a curriculum model and can be viewed as a program model of overall talent development, but unlike the Talent Search Model, the focus is on the development of creative-productive as well as academic giftedness with a greater emphasis on enrichment rather than acceleration options.

The ETM offers three types of enrichment experiences appropriate for students in the school talent pool identified as having high levels of ability, interest, and task commitment. These experiences are designed to encourage students' creative expression and productivity. Type I enrichment provides general exploratory experiences such as lectures by guest speakers, field trips, demonstrations, performances, interests and hobbies, the use of audiovisual materials, and other events designed to expose students to new and exciting topics, ideas, and fields of knowledge not ordinarily covered in the regular classroom. Type II enrichment provides group training activities using instructional methods and materials purposefully designed to promote the development of thinking and feeling processes. In general, training is in the areas of creative thinking, problem solving, communication skills, and skills in learning to learn. Type II activities provide the crucial tools and process skills to enable gifted students to advance to Type III activities. Type I and Type II activities can also be offered to all students in the school, as they will benefit all students. Type III enrichment is defined as individual or small group investigative activities and artistic productions selected and pursued by students who are willing to commit themselves to acquire the advanced content and process training. Each participating student will assume the role of a first-hand inquirer, and think, feel, and act like a practicing professional. By focusing on creative-productive giftedness, students work on issues and areas of study that have personal relevance and can be escalated to appropriate challenging levels of investigative and creative activities.

The RDIM introduces the notion that students are selected for participation in the talent pool on the basis of multiple criteria that include the use of achievement test scores and different indices of creativity as well as teacher-, parent-, and self-nomination. These students are also observed in

classrooms and enrichment experiences for signs of advanced interests, creativity, or task commitment to become involved in Type III creative productivity. Identification continues year-round rather than being confined to the beginning of the school year. Thus, by operating RDIM in conjunction with the ETM, the SEM adopts a more flexible approach to identifying high-potential students, resulting in a talent pool of 15–20% of the school population. In this manner, a student with high achievement test and IQ scores will be automatically considered, enabling those students who are underachieving in their academic schoolwork to be included in the talent pool.

Students in the talent pool are eligible for special services that include assessment on students' abilities, interests, and style preferences, resulting in a Total Talent Portfolio for each student, and curriculum compacting. The Total Talent Portfolio records the assessment of students' strengths that provide the foundation for effective learning and creative productivity. Curriculum compacting, on the other hand, ensures a better match between the achievement levels of individual students and the school curriculum through modifying the regular curriculum by eliminating portions of previously mastered content and by substituting with alternative work.

Recently, Joseph Renzulli and Sally Reis (2009) have developed an Internet-based interactive program called the Renzulli Learning System (RLS) that assists teachers who seek effective tools for differentiation to implement the various components of the SEM. While improved academic achievement and opportunities for creative productivity remain as the major goals of the RLS as those of the SEM, the RLS has a series of metacognitive tools resulting from computer-based learning environments. These metacognitive tools give the added benefits to students by helping them organize and self-regulate their own learning so that they can make the best use of their time, resources, and the cognitive skills that contribute to higher order thinking.

A variety of studies have been conducted to assess the effects of the SEM in schools of varying demographics and in different settings. These studies include evaluation studies, longitudinal studies, studies on curriculum compacting, studies on students' creative-productive behaviors, and studies on underserved gifted populations. These studies have yielded mostly positive results on student motivation and sustained interest in learning. In addition, they have also shown that the SEM can be applied in a variety of school settings, with various student populations, including high-ability students with learning disabilities and those who underachieve in schools. Thus, the SEM has been widely adopted in schools in the US and also has appeals internationally. Variations of the SEM in some forms have been operative in some East Asian countries or regions such as Singapore and Hong Kong.

Nurturing Personal and Social Development

In designing and developing gifted programs for gifted learners, educators generally focus on issues related to what teachers should know about the learning characteristics of students, what skills are needed to provide an appropriate level and instruction for them, and how curriculum and instruction can be differentiated to appropriately challenge them. Very often, social and emotional issues of gifted learners at different stages of development are considered secondary. However, these are important issues, and strategies or efforts to build skills that promote positive social and emotional development among gifted learners should be included as an integral part of any gifted programming.

Developmental Tasks

While gifted children and youth have developmental tasks similar to other typically developing students, some of their developmental tasks may be more accelerated and others may be more difficult to accomplish. For example, gifted children may have more friendship preferences and are ready for more sophisticated types of friendship than their age-peers. Gifted youth may need and could be ready for career development work earlier than other typically developing adolescents. Some gifted children may find it more difficult to develop a strong work ethic because they are placed in a regular classroom with little academic challenge.

Giftedness or talent may also create greater developmental challenges for gifted learners. For example, gifted children may feel their emotions more intensely than other children and may have difficulty learning to manage their emotions. Gifted adolescents may find the achievement–affiliation conflicts particularly acute at a time when they value both achievement and peer relationships but view that they need to choose between being intelligent and being popular. Gifted adolescents may also have greater difficulty in time management because they are taking more demanding classes and engaged in more extracurricular activities. Normally, gifted children and youth are able to master the basic personal and social developmental tasks. However, some may have more difficulties, and others may even have social and emotional adjustment problems that require counseling attention.

Social and Emotional Issues

The reasons that gifted learners may experience social and emotional adjustment problems can be grouped into two types, those arising endogenously from within the individual and those arising exogenously from the environment (Moon, 2008). An example of endogenous challenges is the commonly poor or low social concepts of gifted learners compared with their generally higher-than-normal academic self-concepts. This discrepancy could lead to adjustment difficulties for gifted learners. Another example is the perfectionist tendencies common to many gifted learners. While setting high standards and striving for excellence as positive or adaptive aspects of perfectionism are desirable and should be promoted in gifted learners, excessive concerns and dissatisfaction with effort-performance discrepancy as negative or maladaptive aspects of perfectionism will pose adjustment problems to gifted learners. A third example is related to the fact that some gifted learners are twice-exceptional students with co-occurring giftedness and disabilities. A student who is intellectually gifted and has an attention-deficit/hyperactivity disorder is twice exceptional, as is a spatially gifted student who also has dyslexia. Very often, twice-exceptional students may struggle

with peer relationships, and therefore are often at risk for emotional disorders.

In addition to endogenous challenges, there are exogenous or environmental factors affecting the social and emotional development of gifted learners. These exogenous influences mostly come from the family and school environments. Examples of exogenous challenges from the school include bullying by peers related to the gifted learner's giftedness and inappropriate school placements, where a highly gifted student experiences boredom or social rejection in a regular classroom. Families that are supportive and organized, yet allowing for individual independence and personal growth, affect positively the social and emotional development as well as academic talent development of gifted learners. However, some families are less functional, and families with gifted children are vulnerable to some additional negative family dynamics. One notable negative family dynamic is called 'parentification,' where gifted children are given too many family responsibilities very early in their lives because they appear so adult in their language and behavior. Apart from these endogenous and exogenous challenges, it has to be noted that negative influence on gifted learners' social and emotional development could arise from the interactions between the characteristics of students and their environments. An example is underachievement. In some cases, the causes could be more internal, as for twice-exceptional students, and in other cases, the causes could be more external, as for highly gifted students placed in regular classrooms. Nonetheless, gifted learners may need the attention of teachers, parents, and counselors to help them cope with problems in their social and emotional development.

Intervention Strategies

Gifted learners need to come to an understanding and acceptance of their giftedness or exceptionality, their intensity and sensitivity of feelings, and their need to cope with social and emotional issues arising from their family and school environments. Different levels of problems in social and emotional adjustment may require different intervention strategies from teachers and counselors. Experiential learning activities such as problem-based learning, independent study, service learning, and simulations can be integrated into any content area. These activities develop students' personal and social competence by activating their emotions, encouraging their social interactions, and facilitating their self-direction. Affective curriculum provides more explicit and direct instruction in specific personal, social, and emotional skills such as skills in regulating emotions, mediating conflicts, and setting priorities. While these direct and indirect instructional strategies are helpful in preventing social and emotional adjustment difficulties in gifted students, more severe adjustment difficulties may require counseling or therapeutic interventions using individual, group, and family counseling. Preventive counseling strategies, such as support groups, bibliotherapy, and videotherapy, can be helpful in promoting positive social and emotional development in all gifted learners.

Thus, a comprehensive and well-balanced gifted program should always have a strong affective orientation and nurture the social and emotional development of gifted students.

Trends and Future Directions

Gifted education has a history of about 90 years counting from Terman's time. During this relatively short span of time, it has evolved from education aimed to provide services to a small selected group of children and youth identified as gifted or talented to talent development for all students. Thus, gifted education, within this framework, allows that an equitable pursuit of excellence be applied to all students, including the at-risk and less able, the able, the highly able, or the gifted and talented. This extension could be viewed as an effort to resolve societal concerns about the controversy between equity and excellence, but has a lot to do with the broadening of the conception of giftedness and talent in association with the multidimensional conceptions of intelligence. The conventional notion of intelligence as a single quality that is manifested throughout a person's intellectual performances, measurable by a unitary quantifiable index called IQ score, and present as a potential early in life or not at all is viewed increasingly as an inadequate measure of giftedness. Over the decades, the defining qualities of giftedness have been expanded to include, among others, task commitment, mastery orientation in motivation, different modes of thinking, high self-concept, and creativity, qualities that emphasize the nurturing aspects of giftedness (see Sternberg and Davidson, 2005).

Although some education practitioners today because of convenience or tradition still focus only on intellectually gifted children and youth and identify them using a high IQ score (e.g., 130), there is an increasing acceptance of a broadened notion of giftedness and multidimensional conception of intelligence among educators in the field of gifted education. It is expected that the trend of basing education practices on broadened notions of giftedness will continue, and further broadening will take into consideration different conceptions of giftedness in different cultural settings.

Apart from the multicultural considerations in broadening conceptions of giftedness, there is also a trend of seeking explanations of giftedness based on current knowledge of brain functions from neurology or neuropsychology (see Shaw et al., 2006). The kinds of questions asked could be: how is giftedness or talent represented on the brain level, could giftedness be simply accounted for by 'neuronal resource' as suggested by, for example, more active right hemisphere, or could the 'neural or neurocognitive efficiency' account address differences between the talented and the nontalented while working on identical tasks? Further, it is believed that being sensitive to the cognitive structures of the gifted or how gifted learners process, organize, and deal with incoming information and knowledge, and their cognitive preferences or styles is important for optimizing learning with gifted learners. Thus, the practical applications of increasing knowledge of brain functions in studies of learning in gifted learners will continue to develop into a major trend in gifted education in the next decade (see Sousa, 2003).

Another major trend over the next decade is likely to be the increasing use of instructional communication technology based on advances in information technology (see Pyryt, 2009). Applications like Renzulli's RLS as enrichment strategies to maximize the creativity and potential of gifted learners are likely to continue and become more complex and sophisticated.

Computers and software will certainly be utilized to do a variety of projects to transmit knowledge and enhance skills. The Internet has provided a wealth of information, and will continue to open many doors for teachers and gifted learners not only in teaching and learning per se but also in mentoring or telementoring. However, teachers and students alike need to be using technology more efficiently, effectively, and consistently, and to keep up with innovations in technology related to the Web in the future.

Predicting the future is fraught with uncertainties and what could be more certain will be the inevitable great changes in the landscape of gifted education. With optimism, the changes should be positive. Gifted education will move forward with better understanding of giftedness or talent, including but not restricted to multicultural and neuropsychological considerations, and with more and effective evidence-based strategies or options for the education of gifted and talented children and youth and for talent development in all students.

Abstract

Geography of education focuses on spatial variations in the provision and consumption of education, on the impact of local milieus and social environments on educational attainment, on spatial variations of the sociodemographic structure of the teaching profession, on the influence of policies and demographic change on location patterns of schools, on the mobility of scholars and students, and on other issues of education where spatiality, place, spatial relations, and environments play an important role. As educational achievement strongly affects a person's social status and chances on the labor market, an education-oriented approach can be applied to many topics of geographical relevance.

Geography of education focuses on spatial variations in the provision and consumption of education. It analyzes the impact of local milieus, spatial settings, and social environments on educational attainment; studies spatial variations of the sociodemographic structure of the teaching profession; deals with the influence of policies and geographical structures (e.g., population density, distribution of settlements, transport system, and employment structures) on location patterns of schools; studies the mobility of scholars and students; and explores the impact of cultural values as well as political, economic, societal, and demographic change on educational systems. As educational achievement strongly affects a person's social status and his or her chances on the labor market, and as knowledge is the basis of human action, an education-oriented approach can be applied to a great number of topics relevant to human geography. So far, the vast majority of publications in this field dealt with formal education, but nonformal education and various forms of preschool education and child care (see, e.g., Ball and Vincent, 2007; Holloway et al., 2010) also belong to the research issues of geographies of education.

For various reasons, the educational system has again and again been in the spotlight of politics. It displays power relations between center and periphery, and indicators of educational attainment have frequently been used as a means to uncover social and economic inequalities, racism, and discrimination of ethnic minorities. In many new nation-states, the primary functions of the school system were not only to remove illiteracy and create a well-educated labor force, but to consolidate administrative power, support national identity and hegemonic culture, and assimilate ethnic minorities (Freytag, 2003). Therefore, the language of instruction, the selection of teachers, and the spatial organization of elementary schools have been of paramount political importance both for state nationalism and nationalist movements as well as for cultural emancipation of ethnic minorities.

The quick expansion and specialization of research has split up the wide field of geography of knowledge and education (as it was introduced in the first edition of this encyclopedia) into geography of education in the narrow sense, geography of knowledge, and geography of science. Innovation studies, cluster and network studies, research on creative milieus, labor markets and migration, and many other research fields of human geography developed likewise strong interests in spatial disparities of knowledge, skills, and educational achievement. The following sections will focus on geographies of education in a narrow sense.

Early Roots and Development of Geography of Education

Early historical roots of empirical research about spatial structures of education can be traced back to the first half of the nineteenth century. Some of the social problems associated with early industrialization such as poverty, child labor, crime, alcoholism, and a lack of decent housing generated an interest in moral statistics. Many nineteenth-century social reformers believed that such social problems were caused by ignorance and a lack of moral education. They therefore started investigating into the social and spatial variations of illiteracy and educational attainment, spatial inequalities in the provision and quality of various types of schools, the skills and salaries of teachers, the availability of books in households, and other elements to describe the cultural and economic settings of neighborhoods (Marsden, 1987; Meusburger, 1998: pp. 191–195).

France is the first country where regional differences in illiteracy were studied in a nation-wide and comprehensive way. The main sources of these studies were examinations of military recruits and marriage registers, both of which contained data on the ability to read and write (Furet and Ozouf, 1977; Heffernan, 1989). In 1826, Charles Dupin published the *Carte figurative de l'instruction populaire de la France*. This map (reprint in Meusburger, 1998: p. 193) revealed remarkable regional disparities in educational attainment between northern and southern France. The tables added to this map compared the educational attainment, the number of patents for inventions, and the membership in the Académie Française with various economic indicators suggesting a high correlation between the population's educational achievement and the economic performance of a region.

In the United Kingdom, a number of Statistical Societies emerged in the 1830s and 1840s to study the living conditions and social situation of the poor and to foster social reform. Literacy was again a main concern of these

studies. J. Fletcher (1849: p. 176) published a map on *Ignorance in England and Wales* in the *Journal of the Statistical Society of London*'. (A modified version of the map was published by Hoyler, 1996: p. 188.) When C. Booth analyzed poverty in London, he used various educational indicators on the scale of neighborhoods.

However, apart from occasional early studies, human geography neglected the field of education until the 1960s. One of the exceptions was the Department of Geography, University of Chicago, where E. Parker and Ch. Colby supervised after World War II four PhD theses about "educational land use." Three of them (by H.H. Gross, E. Eisen, and A.K. Philbrick) were published in the "University of Chicago, Department of Geography Research Papers" between 1948 and 1949 (for details see Meusburger, 1998: pp. 204–205).

The interest of geographers in education grew when the 1960s and 1970s brought in many countries an unprecedented expansion of the educational system, a steep increase in university enrollment, the establishment of many new secondary schools and universities, and the need to reorganize the location patterns of elementary schools. This boom in expanding, modernizing and reorganizing educational systems was also nourished by emerging discourses about human resources, brain drain, postindustrial society, knowledge economy, and the legitimacy of social and spatial inequalities. In this period, locations for new schools and universities had to be negotiated, the closure of small elementary schools had to be vindicated, catchment areas and student transport had to be reorganized, and the reasons of intolerable spatial disparities in educational attainment had to be explored in order to counteract them. As these tasks needed competence and experience in geography and urban and regional planning, a sensitivity for the importance of local identities and local milieus, as well as detailed knowledge of the history, culture, and economy of the towns and regions in question, geographers soon became involved in applied educational research and regional educational planning. In the 1970s and 1980s, social scientists became increasingly aware that the famous slogan 'place matters' has a special relevance in education and that residential location, segregation, ethnic diversity, and regional mobility affect education in various ways (Gordon and Monastiriotis, 2007: p. 1204).

One of the first and most influential pioneers of the newly emerging field of geography of education was the German geographer Robert Geipel (born 1929), who focused his research from the early 1960s to the 1990s almost exclusively on geography of education (Geipel, 1966). He was both full professor of geography at the Technical University in Munich (1969–94) and director of The Bavarian State Institute for Higher Education Research and Planning (in Munich (1982–94)). In these functions, he had close scientific relations to the pioneers of this research field in other countries and disciplines; together with the Academy for Spatial Research and Planning in Hannover he organized long-term interdisciplinary working groups on 'spatial educational research.' In the 1970s and 1980s, dozens of German, Austrian, and Swiss geographers got involved with geography of education. As a result, the Association of German Geographers founded 1983 a working group 'geography of education' that is still very active today and attracts not only human geographers, but also social and educational scientists.

In United Kingdom, the early pioneers of geography of education in the 1970s and 1980s were G. Hones, W. Marsden, R. Ryba, W.T.S. Gould, L. Bondi, and H. Matthews. However, the boom of education-related publications of British geographers started only in the 1990s, and the vast majority of these publications restricted their citations to English-language publications (see review articles of Hamnett et al., 2007; Hanson Thiem, 2009; Holloway et al., 2010; Holloway and Jöns, 2012; Taylor, 2009).

Main Research Topics

In its early period between the 1960s and late 1990s, geography of education predominantly focused on the spatial organization of school systems (size, location criteria, and catchment areas of schools and universities); on the reasons and consequences of spatial disparities in educational attainment; on the social composition of schools (measured by the educational achievement and occupations of both parents); on school segregation and student transport; on spatial disparities of vertical social intergenerational mobility (comparison of educational achievement of parents and children); on spatial variations of professional skills, sociodemographic structures, and the feminization of the teaching profession; on spatial patterns of expenditure on education; on spatial impacts of various educational policies and school planning concepts; on relations between communities and schools, especially on the social, cultural, and economic effects of school closures on communities; on the impact of educational achievement on professional careers and migration; on the role of schools in ethnic conflicts and 'nation building'; on relations between illiteracy and economic development; on the spatial distribution of jobs for highly and lowly skilled employees; on theoretical concepts explaining the spatial concentration of jobs for highly educated people; on career mobility and networks of scientists and highly skilled professionals; and on the correlation of different levels of educational achievement with unemployment, female employment rates, housing quality, reproduction rates, and many more variables (for details see Bondi and Matthews, 1988; Kramer, 1993; Meusburger, 1980, 1998; Schmude, 1988; Taylor, 2009). Already in this early period, many geographers situated educational attainment in a very broad economic, social, cultural, and political context; they identified a large range of factors affecting the location pattern of elementary schools, the mobility of university graduates, and other structures of the educational system (Jahnke, 2005; Mayr and Nutz, 2002; Meusburger, 1998).

Since the end of the 1990s, new research questions and new theoretical approaches have developed. Some of these new approaches deal with normative understandings of childhood, treat young people as the subjects rather than objects of education, deepen the understanding of children's spaces of learning, attend to (gendered) identity construction in schools and focus on various aspects of nonparental child care provision, to name just a few (for details see Holloway et al., 2010; Holloway and Jöns, 2012; Matthews and Limb, 1999). Other new research activities focus on the neoliberal 'international education industry' worth an estimated US$ 100 billion (Waters, 2006) and its consequences. According to Waters

(2006: pp. 1046–1049), the establishment of offshore schools and universities overseas first of all has the aim to attract fee-paying (revenue generating) students, but it also creates new geographies of social exclusion within 'student sending' societies.

Varying Priority of Research Questions

The priority of research questions varies not only over time but also from one country to the other. Priorities depend on whether elementary education has a centralized or decentralized governance; which administrative authority (local community, district, province, state, or nation) establishes, finances, and controls various types of schools or selects and pays teachers; whether elementary school catchment areas are defined by school administrations or are the result of parents' decisions; how pupils of different ability are distributed across different types of schools; whether the selectivity of schools is based on the children's abilities or the financial resources of parents; whether a society has a high or low degree of social inequality, ethnic diversity, and vertical social mobility; whether competition for pupils among schools is open or not; whether the ethnic composition of a population is a source of social conflict or not; whether the 'problem areas' of education or the socially deprived areas are rather in urban or rural regions; and which data sources are available to scholars.

In the United States and the United Kingdom school segregation, desegregation bussing, the competition between nongovernment and state schooling, educational inequalities that arise from residential sorting, the flight from working-class schools, repositioning inner-city schooling, relations between family income and educational attainment, and the neoliberal education market have been major research themes (Gibbons and Telhaj, 2007; Gulson, 2007). In other states that have no tuition fees, a less hierarchic class society, less segregation, or a high-quality state schooling, the focus has been on other topics. This had the consequence that different research cultures and citation networks developed within geography of education, and that review articles focusing on developments in one nation or on publications written in one language are bound to fail when they generalize their findings and arguments. In order to avoid such national specialties, the following sections discuss only three research topics of general relevance.

Organization, Size, and Location Patterns of Elementary Schools

The location, organizational form, and minimum size of elementary schools and the daily transport of young children to distant schools are heavily contested in many countries. Many conflicts between communities and school administrations have arisen from the fact that some educational planners or school administrators had little sensitivity for regional and cultural diversity or for the importance of local identities and the symbolic meaning of places. Some politicians and administrators have not been aware that the planning principles and guidelines concerning the location and organizational structure of schools, minimum class size, and even the training of teachers should be flexible and adaptable in order to account for local requirements. Sparsely inhabited rural areas suffering from depopulation had to respond much earlier than did more densely populated urban agglomerations to falling school enrollment numbers, fiscal constraints, and the difficulty of attracting skilled teachers. One- or two-class elementary schools in rural areas, where two to four grades are taught in one classroom, need different teaching methods and differently trained teachers than large urban schools, in which each grade is taught separately in a classroom.

In rural areas of many states, two different concepts of regional educational planning confront each other (for details see Kramer, 1993). The concept of centralized large elementary schools to which pupils are transported over long distances by school buses or parents, claims to be financially more efficient, to offer more flexibility in the assignment of teachers, to offer a larger variety of study courses, to create more social equality, to offer a higher quality of education, and to be 'more modern.' The negative implications of this concept, such as transporting 6- to 10-year-old children over large distances in social environments unfamiliar to them, confronting the children with values contrary to those of their family environment, exposing them to emotional stress, and cutting down a large part of their leisure time are usually overlooked by the proponents of this concept. Neither do they seem to care about the long-term negative effects of closing the only elementary school in a village.

An alternative view advocates for small decentralized elementary schools located in (or near) the villages and towns where the 6- to 10-year-old pupils live (Kramer, 1993). Because of smaller classes, this approach requires more teachers and more financial resources per 100 pupils than for large urban schools; it is less flexible in the assignment of teachers and demands differently trained teachers. However, proponents of this concept claim that the pedagogic advantages and many positive extracurricular effects outweigh the higher costs. Adherents of this approach have a different view of childhood, are more sensitive to spatial disparities and local needs, view as negative the experience of children with long-distance bussing, and are primarily interested in the relationship between educational provision and community coherence (see also Bunar, 2010). They maintain that in peripheral rural villages, elementary school teachers play an important extracurricular function and have a greater impact on the community than such teachers have in large cities. If sparsely inhabited rural areas are successful in attracting skilled teachers, their schools will be indispensable elements of communal infrastructure; their schools will be the places where local identity and social networks are formed and strengthened, and where cultural activities and sensitivity for regional environmental problems are nurtured. In such social milieus, skilled teachers are still key persons in the community and have to fulfill many out-of-school functions (e.g., conductor of the church choir, soccer trainer, leader of the amateur theater, conductor of the local brass band, or leader of the voluntary fire department). In urban areas, these functions are more or less professionalized so that the extracurricular roles of teachers are much less needed. In a sparsely inhabited rural area, the closure of an elementary school and the disruption of children's living and learning

spaces have much more negative social, cultural, and economic effects than in a large metropolitan area.

Clashes between these two concepts gain a special political explosiveness in multiethnic or multilingual areas. Since the early beginnings of compulsory schooling in the late eighteenth or early nineteenth century, administrative control of school systems and the language of instruction in elementary schools emerged as focal points of conflict in bilingual areas. During the nation building process, one of the primary functions of state elementary schools was to support national unity and to assimilate ethnic minorities. The language of instruction in the first grades of elementary school was of paramount instrumental value in suppressing or emancipating ethnic minorities. School authorities could easily disadvantage autochthonous ethnic minorities by raising official standards for the minimum school and class size, by forbidding minority languages in instruction, and by assigning teachers who did not speak the language of the minority pupils and were not familiar with their culture.

Those autochthonous minorities who are not allowed to have elementary schools teach in their mother tongue, who are offered badly equipped schools and poorly qualified teachers, and whose cultural heritage is devalued or omitted in schoolbooks, may demonstrate low performance, low commitment, low aspirations, and high resentment, which then become justifications for further discrimination and reduce minority people's power to compete in the labor market on equal terms for jobs (for details see Freytag, 2003; Gamerith, 2006; Meusburger, 1998).

Also in urban areas, educational policy should be coordinated with housing policy, urban planning, and urban renewal in order to be successful. Without improving an area's housing quality and reputation, educational policies will not be able to increase low educational attainment in that area (Giband and Lacquement, 2007; Gordon and Monastiriotis, 2007; Gulson, 2007).

Spatial Disparities of Educational Achievement and Attainment

Indicators of educational achievement describe the final result of an educational process. Indicators of educational attainment are used to describe a current status in an ongoing (unfinished) process of education. As some indicators of social status such as income, consumer behavior, life style, or housing quality are not as regularly surveyed by official statistics as is educational achievement or at least not published for small administrative units, various forms of educational achievement or attainment became significant and frequently used indicators describing spatial variations of social status, social inequalities, and social processes such as vertical social mobility. This use is justified by the fact that well-chosen indicators of educational attainment (achievement) highly correlate with all other indicators of social status.

The educational achievement of an adult population is measured by indicators such as the proportion of illiterates, the proportion of the adult population who completed a certain level of education (e.g., proportion whose highest level is elementary school, vocational school, college, or university), or by median school years completed. Indicators of educational attainment illustrate the flow of students through the hierarchic structure of an educational system, as well as the students' performance in various types of schools. Spatial disparities in the educational attainment of pupils can be measured by indicators of participation, performance, success, and failure. Some of the most frequently used are the proportion of an age group attending a certain type of school, transition rates (enrollment rates) of a 1-year age group to various institutions of higher education, school survival expectancy or persistence of school attention (how many years do pupils remain in the school system?), school performance indicators such as results of general certificates or achievement tests (e.g., in the United States 'National Assessment of Educational Progress'; in the United Kingdom 'Pupil Level Annual School Census' or results of 'General Certificate of Secondary Education'), the share of dropouts and truants (school absence rates), or out-of school-suspension rates.

The usefulness or explanatory power of these indicators is not stable over time and space. First, it is influenced by the differentiation and selectivity of the school system. A highly differentiated and selective school system provides more significant indicators of educational attainment than a less differentiated and a less selective one, where almost all pupils successfully achieve high levels of education. Second, most indicators have a kind of life cycle and lose their explanatory power after a certain period of time. In some (developing) states, illiteracy rates may still be the most significant indicator to describe socioeconomic disparities within a region, but in many other states illiteracy rates are irrelevant because literacy is so widespread.

Spatial disparities of educational attainment are influenced by at least eight groups of factors (Meusburger, 1998; Webber and Butler, 2007).

1. The foremost factor is the sociocultural milieu in the family, for example, parental social status, educational achievements and professions, their cultural values and attitudes toward education, the time they spend with their children, and the encouragement they give their children. Families as educational settings contribute to the development of the cognitive abilities, motivations, and aspirations of children. However, the sociocultural milieu should not be equalized with the financial situation of a family. It is true, that in many cases there is a close positive correlation between affluence of parents and educational attainment of children. But affluence is only a proxy variable for other factors, and there are plenty of examples of very rich communities showing low enrollment rates in institutions of higher education.
2. Qualification of teachers and their interaction with the community. The impact of teachers on the educational performance of talented pupils can hardly be overestimated. However, not all teachers have the same training and skills, not all teachers are willing to commit themselves to the needs of the local community, and not all teachers are socially accepted by the community. High turnover rates of teachers are usually an indicator that they are not satisfied with the situation at their school. High rates of extracurricular activities of teachers for their pupils or their community signal a high degree of commitment.

3. School composition effect. Schools differ strongly with regard to the social background and abilities of their pupils. As high-attaining and low-attaining pupils are sorted into different schools after passing elementary school (see Gibbons and Telhaj, 2007: p. 1282), school composition shapes the values and attitudes prevailing among peer groups and has a strong influence on educational attainment, both in countries with and without school fees. Even on the same level of schooling (e.g., secondary schools), small differences in the curricula (e.g., a focus on modern languages or on natural sciences) result in significant differences in the social composition of the students (Meusburger, 1980: pp. 159–179).
4. Neighborhood effect. The type of neighborhood in which a pupil grows up is one of the most effective predictors of a pupil's educational performance (Webber and Butler, 2007). The neighborhood effect is partly based on the social composition of the residential population. But it also consists of close social or cultural relations, shared values, a sense of belonging to a local community, and social control within the community. Emotional attachment to a place, the feeling of safety among 'our own' people, the support of strong social networks, and the fear of becoming an outsider in schools located in other areas seem to be strong motives for parents from ethnic minorities and working class families to keep their children in low-performing schools in their own neighborhood even if they are free to opt for a school in another area (Bunar, 2010: p. 142).
5. Organizational structure, governance, and equipment of schools. The size of classes (student–teacher ratio), the provision of a school with teaching aids (library and laboratories), the governance, ethos, and reputation of a school attract and keep skilled teachers and influence the quality of their teaching and as a consequence the interest of pupils in special topics. Contrary to the opinion of Gulson (2007: p. 1381) and others, a larger school is not necessarily a better school. A larger curricular and extracurricular choice does not automatically imply that the quality of educational provision or the educational performance of pupils improves. Organizational structures of schools should not be studied in isolation from other factors mentioned here.
6. Spatial variations in the provision of higher education. Urban agglomerations provide a greater variety of secondary schools and institutions of higher education than do peripheral rural areas. For upper class parents, the distance to school has no or little impact on their choice of secondary schools, whereas long distances to the next secondary schools deter parents from lower social strata from sending their children to these schools, especially in ethnically segregated areas and in areas where free school transport is not available.
7. Employment patterns, diversity, and qualification structure of jobs offered in a town or region. A highly differentiated economy, the availability of many highly skilled jobs, and high vertical social mobility influence the occupational and educational aspirations of children by offering them more attractive role models and more economic prospects than a lower skilled and less differentiated labor market would do.
8. Political control, power relations, and state intervention. In the eighteenth- and nineteenth-century Europe, territories under a strong feudal control with a late abolition of serfdom had much lower school attendance rates and became literate much later than did areas with an early introduction of democratic elements and prospects of vertical social mobility. The nineteenth and twentieth centuries offer many examples of harsh state intervention. Between 1740 (South Carolina) and 1838 (Ohio), a number of states in the United States adopted compulsory ignorance laws, which excluded 'negro' children from public schools or even stated that any person who taught slaves to write or employed slaves as scribes would be fined or imprisoned for up to 12 months. In the twentieth century, communist regimes prohibited pupils from ideologically unreliable families from attending grammar schools or studying at universities, and fascist states openly restricted the proportion of Jewish students at their universities.

Correlations between single variables and educational attainment often lead to ambivalent and inconsistent results. Most of these factors have mutually reinforcing effects. It is the local combination of multiple deprivations or of multiple privileges that produces a local milieu or knowledge environment entailing low or high educational attainment. As high or low educational attainment tends to occur in many different contexts and for quite different reasons (Webber and Butler, 2007: p. 1241), an investigator needs deep knowledge of the society, culture, economy, and value systems of the neighborhoods, places, or regions in question when interpreting causal relationships.

Institutions of Higher Education

Some of the research issues already discussed can also be applied to universities and other institutions of higher education. However, universities offer additional challenges for geography of education, and they are also in the focus of geography of science. What makes a university attractive for students and scholars? Which factors are responsible for the intellectual ups and downs of universities? Why did some newly founded universities develop successfully, whereas others did not? Why are Nobel Prize winners or other outstanding scholars confined to such a small number of universities? How can a local knowledge environment affect research processes? What impact does a university have on the economy, society, and culture of its town or wider region? What is the role of universities as key actors in the knowledge economy? How do transnational knowledge networks of scientists evolve, and what long-term consequences do they have? What factors influence the spatial mobility of scholars and students? These questions indicate that the generation and diffusion of scientific knowledge is influenced by local milieus and spatial relations; that scientific practices vary from place to place; that social environments have an impact not only on generating, evaluating, and legitimizing new scientific knowledge, but also on the reading and interpretation of texts; that universities are not simply locations but social spaces, epistemic venues, and knots

of scientific networks (Livingstone, 1995; Meusburger and Schuch, 2012).

What does a scientific milieu or knowledge environment consist of? Scholars and students depend on financial resources, libraries, laboratories, and buildings; their goals and fields of interaction are influenced by evaluators, role models, critical audiences, institutional regulations, informal expectations of their social environment, and a multitude of other factors. The knowledge environment of places can have a decisive impact on the research interests of scholars, their motivation and acquisition of professional competencies, their integration into important networks, and the encouragement they receive from key people in a particular field of study. However, a scientific milieu is not an independent variable that has predictable effects. It is rather a local potential or an offer of chances, stimuli, support, and challenges, which will be taken advantage of by some scholars and ignored by others. Whether and how a person makes use of a milieu's potential depends on his or her goals, cognitive abilities, and social relationships.

Universities differ with regard to the career histories, regional provenance, and geographical mobility of their professors and lecturers, the social origin and catchment areas of their students, and the spatial dimension of their academics' networks and scientific cooperation. The higher the scientific reputation of a university and the larger its resources, the more it acts as a magnet of talent and brains, the more it will be able to attract scholars from prominent other universities, the more international will be its catchment area of outstanding students, the more it will disseminate ideas and scholars all over the world, the more professorships are offered to its young researchers by other universities, and the more impressive are its global networks. However, the spatial expanse of scientific relations and the areas from which a university draws its professors and students can also be severely influenced by political conflicts (e.g., Cold War, Iron Curtain), language barriers, as well as the economic and political situation in the home countries of scholars and students (Meusburger and Schuch, 2012).

Since medieval times, scholars and students have been expected to be geographically mobile for various reasons. First, mobility can inspire new ways of thinking and bring about new relationships and cooperation in the world of academia. Scholars should gather personal experience in different departments, tackling a variety of challenges and familiarizing themselves with issues and methods they have not yet encountered at their present place of work.

Second, in order to remain competitive, a university's knowledge environment must continually be replenished by the best available talent, who can bring in new ideas from elsewhere. Faculties systematically favoring their own former students for professorships run the risk of narrowing their scientific perspectives, and eventually diminishing the quality of their scientific performance. An academic who has worked successfully at other universities generally has a greater range of experience, more extensive personal networks, a broader methodological spectrum, and a better academic reputation than one who has worked in only one institutional setting.

Third, the career mobility of a scholar can be used as one of many indicators of his or her scientific potential. If two or more faculties have confirmed that the scientific achievements, competence, and other merits of a scholar warrant that person's appointment to a position as lecturer or professor, then the uncertainty about that person's scientific potential is much lower than if confirmation came only from the same faculty where the candidate had studied and graduated.

Fourth, creative concepts, innovative methods, and revolutionary scientific findings that contradict common paradigms of mainstream science are not immediately accepted. In spite of the Internet, it can take years or even decades before new theories or methods are recognized within one's discipline or in adjacent ones. The surest way to transmit epochal scientific findings and methods from place A to place B is the geographic mobility of scholars who possess the relevant knowledge.

Further Perspectives

It would be futile to establish a list of emerging fields in geography of education. However, the development of international student flows and the impact of alumni networks on economic and political decisions; the impact of political ideologies on educational systems and educational priorities; the varying role of the meritocratic principle in different societies and its consequences for economy and society; the relevance of educational inequalities in political discourses; the increasing internationalization, neoliberalization and marketization of higher education and its consequences; the schooling of underprivileged ethnic minorities (e.g., Roma in Europe) and of pupils with special needs; the definition of knowledge environments and their impact on learning processes; spatial differences of philanthropic support of education; and many other questions need to be studied more intensively.

Abstract

While education as a social practice has occurred at all times and social settings, this article focuses, in Section The Rise of the Modern Educational System, on a crucial stage in the specifically modern transformation of that practice, namely its crystallization, from the late eighteenth century onward into fully institutionalized and increasingly inclusive 'national systems.' This process of educational system formation gave rise to the emergence not only of educational theory more generally, but also of history of education as a particular field of study. As a consequence of these origins, the field has oscillated up to the recent past between education and history, i.e., between systemic self-reflection committed to educational ideals and reform and more detached research committed to the rules of historical method. Section History of Education in Connection with Systemic Self-Reflection examines the institutional conditions and disciplinary models that have contributed to shaping the history of education into either an adjunct to educational theory or a specialized branch of historical study. Finally, Section History of Education as a Field of Social Science Study reviews the important renewal and wide-ranging diversification the field has experienced from the 1960s onward as a consequence of the influx of concepts and methods stemming from innovations both in social and intellectual history and in the social sciences more generally.

'History of education' is an ambiguous term in at least two respects. First of all, the term has come to designate different levels of reality. On the one hand, it refers to education as a universal social practice and to the manifold forms and successive transformations that this practice has experienced over time. On the other hand, it refers to a field of intellectual activity, namely a branch of historical study, devoted to describing, interpreting, and analyzing this practice. Obviously, both levels are not disconnected from each other. Rather, it was a crucial stage in the transformation of the former, namely the crystallization of education, into fully institutionalized and increasingly inclusive 'national education systems,' which gave rise to the emergence, not only of educational theory in general but also of the historical study of education in particular. This historical connection, however, gave rise to yet another ambiguity, an ambiguity inherent in the emergent field of study as such. From its very origins, this field has oscillated between different disciplinary orientations, namely education and history, i.e., between systemic self-reflection committed to educational ideals and reform, and more detached research committed to the rules of historical method. Against this background, the article briefly describes the process of educational system formation and some of its key features (Section The Rise of the Modern Educational System) in order then to set out the institutional conditions and disciplinary models that have contributed to shaping the history of education into either an adjunct to educational theory (in terms of, e.g., *Geschichte der Pädagogik* or *histoire de la pédagogie*) or a specialized field of historical study (in terms of, e.g., *Historische Bildungsforschung* or *histoire 'historienne' de l'éducation*) (p. 2). The article then goes on to describe in greater detail the important renewal the field has experienced, especially from the 1960s onward, as a consequence of the influx of concepts and methods stemming from innovations both in social and intellectual history and in the social sciences more generally (Section History of Education as a Field of Social Science Study).

The Rise of the Modern Educational System

Although education has occurred, and continues to do so, in manifold forms and at all times – in families, through catechizing, at the workplace, in youth clubs and organizations, or in borstals – education in modern times has by and large become institutionalized in the form of large-scale public systems of education. These constitute the modern type of educational organization *par excellence* (Thomas et al., 1987). Processes of the formation and eventual consolidation of 'the modern educational system,' while starting toward the end of the eighteenth century, came to completion only toward the turn from the nineteenth to the twentieth century (Müller et al., 1987). Moreover, educational system formation was only possible as a component of more encompassing processes of social transformation, and of concomitant processes of state and nation-building, which led to the specifically modern pattern of societal organization explained as 'functional differentiation' by recent social theory (Luhmann, 1982). Drawing on related concepts, one may characterize educational system formation by key features such as *inclusion*, *nationalization*, and the system's *internal articulation* as well as *systemic self-reflection*.

Inclusion refers to one of the central aspects of modern social structures, namely the access of a population as a whole to all of the functionally specific subsystems constituted at the level of society. More precisely, inclusion means the universalization, not of so-called 'service roles' such as those of a politician, a physician, or a teacher, but of the corresponding 'service-receiving roles' specific to each of society's subsystems, namely the roles of the electorate, patients, or pupils, respectively. Thus, the educational correlate to the inclusion process at the level of society at large was, in terms common to present-day debates on education and development, the 'universalization of primary education.' This process started in the Protestant countries of central and northern Europe as early as the

seventeenth century; was largely achieved, in most of western Europe, by the end of the nineteenth century; and came to an end, in some countries of southern Europe, Latin America, and Asia, only in the middle of the twentieth century. And yet, it still constitutes an unmet challenge in large parts of the Southern Hemisphere. At the level of national legislation, important steps toward universalizing primary education often went hand in hand with measures undertaken to assure greater inclusion also in the political and legal systems. As illustrated by the historical experience, not only of England and Italy, but in varying forms also of France and Prussia or to some extent Russia, such measures consisted in, e.g., the extension of the franchise or, more generally, steps designed to turn hitherto dependent subjects into national citizens. At the local level, however, national school laws were gradually implemented as an answer to the radically altered communication requirements that were attendant on social structures increasingly characterized by new patterns of differentiation and ensuing processes of rationalization, mobilization, and industrialization. In this sense, the process of inclusion in the emerging educational system corresponded to the gearing of that system to its actual function, for this function consists precisely in laying the foundations of the capability for universal communication across all subsystems of society. In sociohistorical terms, thus, it was essentially the achievement of universal mass schooling that marked the decisive transition toward the constitution of institutionalized education as a modern 'system.'

Nationalization refers to another process that came to fruition from the eighteenth century onward. To the extent that the traditional union of schools and church(es) gave way to the differentiation between education and religion, which were more and more conceived of as distinct spheres of social action and meaning, it was the increasingly rationalized and secularized nation-state that was thought to serve as the natural support and guardian of the education of its citizens. This view was underscored by the fact that the eventual achievement and continuous running of an inclusive educational system presupposed organizational resources and required an administrative infrastructure that no corporate social actor other than the state was deemed able to provide. Alternatively, the state and state-supported agencies were ready to use compulsory mass schooling also for pushing through the realization of more general state-related goals such as social mobilization and equalization, national integration and collective identity-building, or political socialization and indoctrination. Thus, whether in Europe, in the Americas, or in Asia, the realization of an all-inclusive educational system by way of universalizing compulsory mass schooling went hand in hand with the increasing intervention of central state agencies and the building of comprehensive administrative frameworks. Education ministries were established for securing the financial resources and building up the administrative infrastructure necessary in order not only to guarantee generalized supply but also to successfully run standardized networks of institutionalized schooling. Just like the realization of compulsory mass schooling, this process took more than a century to come to completion. It was a long way, indeed, from late-eighteenth-century programs of establishing a coherent state-run scheme of educational institutions modeled on Catholic Church organization (in the pioneering Italian principalities of Parma and Piedmont and, subsequently, in imperial France) to the all-encompassing organization of institutionalized schooling as a 'public legal organism' (as this accomplishment was acclaimed in late-nineteenth-century social analysis).

The emergent system's *internal articulation* was the inevitable complement to inclusion. Since education systems in Europe were not created in a vacuum, their system formation processes started from quite an array of existing institutions that were stemming, on their part, from premodern establishments such as medieval cathedral schools and Renaissance universities, church-run colleges and academies for the sons and daughters of the nobility, endowed grammar schools and *Gymnasien* established by enlightened princely rulers, as well as municipal petty schools and the nineteenth-century forms of drawing schools, science schools, higher-grade, technical, and vocational schools. It was, then, a significant feature of the differentiation process that, during the initial stage of inclusion and due to such origins, the emergent educational systems were rather decentralized, uncoordinated, and open in their organization. The more the continuing process of inclusion advanced, however, the more acute the need for internal specification and rational articulation became apparent. Specification, on the one hand, implied the removal of ambiguities and unregulated competition between institutions that were to become clearly defined alternative tracks or types of schooling. The systems' articulation, on the other hand, raised the issue of connecting hitherto uncoordinated institutional components with the aim of constructing a rational 'sequence,' or 'ladder,' of successive levels of education. The outcomes of such processes of defining educational systems' institutional structures can then be conceived of as ways of coping with divergent expectations and requirements: with inclusion (by organizing universal access to primary schooling for an entire age-group) and selection (by consecutively channeling pupils into different tracks and levels), or with qualifying for universal communication across all fields of society and inculcating differential 'habitus' as appropriate to particular groups, trades, and areas of activity. As a consequence, the issue of defining an educational system's career sequence has always been closely associated with a nation's public policy in general and with its social and economic policy in particular. This applied especially to the construction of sequence between the 'lower' or vernacular schools (e.g., the so-called 'English' or 'German' schools) and the 'learned' or Latin-based establishments, or between, to take up a graphic phrasing coined by Prost (1968), *l'école du peuple* and *l'école des notables*. Thus, from the late-nineteenth-century 'systematization' of the major western European education systems over the definition, during the first half of the twentieth century, of examination-based transition procedures from the primary to the secondary level of education up to the successive introduction, from the 1960s onward, of comprehensive types of schooling in many, but not all, countries throughout the world, contrasting models and programs for educational sequencing have been at the very core of educational policy debate. At the same time, these models and programs have fostered again and again the production of both educational reflection – particularly reformative reflection – and educational research.

History of Education in Connection with Systemic Self-Reflection

It is a significant feature of modernity that in subsystems of society that have crystallized in connection with the far-reaching transformation processes explained in terms of 'functional differentiation,' system-specific self-descriptions intensify to such an extent that they take the form of explicitly stated reflection theories. This common pattern of self-referential theories of a societal subsystem developed within that system holds true also for educational theorizing pursued within the emergent educational system (Luhmann, 1982). The tremendous increase, from the late eighteenth century onward, in the production of educational ideologies, educational theories, and educational knowledge more generally has to be seen in connection with the growing acceptance of programs and policies fueling the establishment of state-run 'national systems of education.' In particular, the conceptual model of systemic self-reflection intrinsic to the major subsystems of society makes intelligible the institutionalization of educational theory as a field of academic study in close temporal and ideological connection with the passing of the decisive laws on compulsory schooling in most of the western European nations. The historically unprecedented scale of universal mass education, its inclusive character, and, especially in the Catholic countries of southern Europe, its secularized organization not only presupposed an administrative infrastructure of a previously unknown magnitude, but also required the intensification of reflection in new and more sophisticated forms. Moreover, the transition to universal mass education also entailed the need for public legitimization of the new system, not least in the form of throwing into relief distinctive national traditions of education and schooling. Salient examples include the foundation of the *Musée Pédagogique* in France (1879) and of its counterpart in Spain (1882), which were meant to serve as depositories of their respective nation's educational memoirs; the virtual invention of national educational tradition in monumental works such as Gabriel Compayré's *Histoire critique des doctrines de l'éducation en France* (1879) and Ferdinand Buisson's *Dictionnaire de pédagogie* (1887–88); or the launching of the *Monumenta Germaniae Paedagogica* meant to collect 'the materials, scattered over archives and libraries, that are relevant to the history of German education and schooling' (1886–1938).

In addition, the necessities of systematic teacher training and attendant considerations of social utility and responsibility impinged heavily on the emergent forms of the historical interpretation of educational traditions. These necessities and considerations favored a genre of educational history that remained subordinated to the categories and problematiques of systematic – i.e., philosophico-reflective – theorizing, a genre in other words that gave preference to narratives of the great educators and philosophers of the past, and to interpretations of their respective doctrines realized in terms of normative hermeneutics. Interestingly enough, this genre has been common to most European countries. It can be traced from early British works over, for instance, Dutch and Scandinavian examples as well as the impressive range of, in particular, German and Italian histories of educational thought up to recent specimens in quite a number of countries (Heinemann, 1979–85). This genre as well as a good many of the studies commonly assigned to the history of education have aimed at producing – and in fact continue to produce – not primarily historical research in the manner of historians, but, instead, justification and legitimization, the construction of enlightened norm consensuses, and the reinterpretation and reactualization with respect to issues of present-day educational reform and of the normative and theoretical substance contained in historical texts, models, or institutions. In other words, this tradition of an 'educational' history of education – of *Geschichte der Pädagogik* or *histoire de la pédagogie* – has not aimed at a detached historicization of lines of educational thought or of past experiences, but at certain forms of theoretical and normative 'traditionalization.'

Thus, seen from the vantage point of sociohistorical analysis, the history of education closely associated, in terms of institutional and disciplinary affiliation, with educational theory has from its origins shared the ambiguities proper to the latter field. Just as educational studies in general, history of education has oscillated between rigorous research and systemic self-reflection. Accordingly, the field has given room to a considerable variety of constructions of reality, the varying presuppositions of which ensue from their being related to distinct system logics and problem perspectives: to either issues of objective method and explanation as debated from the vantage point of social science research, or issues of meliorism and reform immanent in the dynamics of modern education, and to attendant needs for interpretation, orientation, and professional knowledge. The respective proportions, however, in which these component modes of reasoning have given shape to historical studies on education, arise from an intricate interplay of institutional conditions, intellectual traditions, and disciplinary models (Schriewer et al., 1993). Thus, recent analyses of the state of the art have – on the grounds of reviews of substantive interests, research topics, and methodological approaches that are given preference to as well as of the field's disciplinary status, specialized journals, and associations – contrasted two major models. These are, on the one hand, the German model, which is well represented also in countries such as Switzerland, Austria, and Hungary as well as Italy and Scandinavia, and, on the other hand, the institutional-*cum*-epistemological model prevalent in France and the United Kingdom, respectively (Compère, 1995). In the former model, due to a long-standing tradition of educational-*cum*-philosophical theorizing as well as to the institutional and intellectual integration of the history of education into education as a discipline firmly established in academia, the system-reflection style of educational history described above has by and large prevailed up to the 1970s and still has a strong impact up to the present. By contrast, the tradition of education conceived as a philosophico-hermeneutic field of theorizing gave way to educational studies based on the social and human sciences both in France, from the 1930s onward, and in the United Kingdom, in the aftermath of World War II. Consequently, these developments also facilitated the alignment of historical studies on education with history and sociology proper, and the intellectual opening of such studies to wider sociological and anthropological frames of reference. Thus, in France and the United Kingdom, just as in the United States, history of education has turned into an academic discipline in

its own right, which is fairly independent of educational studies in general, based on its own specialized journals, and elaborated by scholars who are (also) trained as historians. This *histoire 'historienne' de l'éducation* has in turn encouraged initiatives leading to the emergence of a social history-related *Historische Bildungsforschung* also in countries traditionally influenced by the German model.

History of Education as a Field of Social Science Study

Fueled by debates on a 'new history of education,' which arose in the United States at the beginning of the 1960s, conceptual models and methodological approaches heavily influenced by modern social history (*see* Social History), intellectual history (*see* Intellectual History), and the social sciences more generally have since then considerably altered the field. The publication, in 1960, of Philippe Ariès' *L'enfant et la Vie Familiale sous l'Ancien Régime* and Bernard Bailyn's *Education and the Forming of American Society* can be seen as a turning point. A stimulating and intellectually demanding period was about to begin. From the 1960s to the 1980s, the 'new history of education' brought a critical perspective into a discipline that had been dominated by parochialism and myths of progress. Ever since, its repertoire has come to include the *longue durée*, a focus on structures and mentalities, a special attention to serial and quantitative methods, and the ambition of 'total history.' These changes, moreover, are reflected in corresponding shifts from narrative history to problem-centered history, from descriptive to explanatory approaches, and from conceptions of unilinear evolution to a vision of historical processes that emphasize their often conflict-laden, asynchronous nature. While accomplishing such shifts, scholars like Michael Katz and David Tyack, Antoine Prost and Dominique Julia, and Lawrence Stone and Harold Silver have been deeply influenced by social history perspectives. They have turned the legitimizing narratives of the past upside down, providing new arguments about the emergence and development of educational systems, the role of schooling in social reproduction, the educational strategies of various social classes, and the action taken by the nation-state in establishing mass schooling. They accordingly shifted the attention from the evolution of educational ideas to the relationships between education and society.

While in the early 1980s, a sense of accomplishment was shared by a majority of the researchers involved in rewriting the history of education, only a few years later, the resources of the 'new' history of education seemed to be exhausted. The accumulation of data, the considerable increase in well-conducted studies based on extended series of archival sources, and the growing specialization of historical inquiry nevertheless left the impression that educational historians had fallen short of addressing actually meaningful issues. In addition, efforts meant to raise new questions, related, for instance, to minority and gender issues, did not lead to an epistemological breakthrough, but rather to an even wider fragmentation of the field. Innovative solutions were to be found, then, in the adoption of theoretical frameworks and methodological approaches that focus not only on the organization of practices and discourses over time, but also on the elucidation of how these practices and discourses have constructed and reconstructed the individual lives of people and, thereby, social reality. In this sense, educational historians are facing the same challenges and dilemmas as social scientists more generally. To the extent that the difficulties of coping with the plurality of meanings henceforth present in the analysis of social phenomena became apparent, the 'new' complexity of historical work has nourished old suspicion as far as theory is concerned (Lagemann, 2000). The transition from 'history' to 'histories' implies a reconfiguration of the field that invites educational historians to reconceptualize their work and to adopt a more comprehensive approach, shifting from a social history of culture to a cultural history of society (Chartier, 1998). Still, there is no consensus regarding the changes that are occurring in historical studies in education (Cohen and Depaepe, 1996). Nevertheless, drawing on an often used conceptual division between educational actors, school practices, educational ideas, and educational systems, it is possible to identify major tendencies that have come to shape historical research in education (Nóvoa, 1998).

The History of Educational Actors and the Rediscovery of Experience

For a long time, historians have described the history of educational institutions rather than that of educational processes or interactions. Consequently, the history of educational actors has been one of the most neglected areas of research. The rediscovery of the concept of 'experience' opened new possibilities, well illustrated by numerous texts on autobiographies, teachers' professional careers, or students' life stories. One of the reasons why feminist theories have been so powerful in educational history is that they help to reveal histories silenced by traditional narratives. From these points of view, modernity dispossessed the actors of the educational process from their subjectivity through the imposition of a structural logic and a populational reasoning. People were classified as categories (the teachers, the learners, the children at risk, etc.) and managed as populations. However, after a long tradition of conceptualizing the world in terms of structure and representation, time had come to see the world as 'experience.' This implied a new 'epistemology of the subject' that, by dissolving the 'natural' divisions between public and private, discourse and practice, or text and context, prepared the way for a shift toward a self-conscious study of pupils and teachers, and for bringing the individual actor in education back into the historical portrayal. Moreover, new conceptions of the subject and of experience allow attention to be paid not only to living experience but also to the way people elaborate it. Finally, the concept of 'experience' has to be seen not only at an individual level but also in its collective dimension, which is characterized by a redefinition of identities and belongings through the participation of people in different communities of meaning.

The History of School Practices and a New Concept of Culture

The history of school practices is another field that has traditionally been neglected by educational historians. Explanations of this 'black box' phenomenon are directly related to the concept of 'culture.' Schools have always been regarded as places of culture: at first, in an idealistic vision of putatively

universal values and knowledge to be transmitted to the young generations; afterward, in a critical perspective of ideological inculcation and social reproduction. In both the cases, educational historians failed to look at the internal production of a distinctive school culture that is not independent of social struggles and conflicts, but cannot be explained as being merely determined by the external world either. More recent conceptualizations, in contrast, have defined school culture as both an ensemble of norms (which organize the branches of knowledge and behaviors that must be brought into schooling) and an ensemble of practices (which allow the transmission of such knowledge and the integration of such behaviors). Moreover, it is possible to identify tendencies of historical research that successfully try to refocus historical inquiry onto the internal functioning of the school by providing thoroughgoing analyses of organizational structures, curriculum issues, school subjects, and day-to-day realities. Thus, one of the most interesting lines of work tries to understand the permanence of a 'grammar of schooling' that resists changes and reforms. Another line of research focuses on the history of the curriculum, viewed as the outcome of a complex interplay of competing values and traditions. Several authors are voicing the need for deconstructing a 'natural history' conception of the curriculum and therefore seek to problematize the curriculum as text and historicize its evolution over time. A third strand of recent research worth mentioning is concerned with the history of school subjects. Historians are asking salient questions regarding the formation of school subjects, the institutionalization of school knowledge, and the ways in which it helps to organize our understanding of the world. Finally, one should not fail to point out a research trend concerned with the 'silence' observed within the traditional history of education about meaning and culture of classrooms, or the everyday education practice (Grosvenor et al., 1999; Berrio, 2000).

From the History of Educational Ideas to a Sociohistory of Knowledge

In contrast to traditional histories of educational ideas, the 'new' cultural history of education is interested in the production, diffusion, and reception of educational discourses throughout time and space. In other words, it is interested in "a historical imagination in the study of schooling that focuses on knowledge as a field of cultural practice and cultural production" (Popkewitz et al., 2001). Therefore, the research interest has shifted to the discursive practices that regulate schooling, especially in situations of conflict or rupture. In this sense, several authors are calling for a historiography, not of the general terms, but of the conceptual structures that determine educational discourses, and for analyses, not of prominent ideas, but of fields of historically defined discursive problematiques. Such an approach is also important for analyses of the roles played by educational experts in providing 'legitimate' or 'scientific' interpretations of school realities. It helps to understand the original institutionalization of educational studies, not as a narrative of intellectual progress, but as a form of 'governmentality.' The question is not how to identify different ideas, but how to apprehend the rise of expert systems of knowledge (Drewek et al., 1998). The same holds true for the analysis of the complex transformation procedures that change academic subjects (integrated into their distinctive conceptual spaces) into school subjects (integrated into the arena of schooling), or for the study of the production and diffusion of textbooks that are not simply 'delivery systems' of factual information, but the results of cultural constructions imposing particular ways of seeing and interpreting the world. In this sense, knowledge has increasingly come to be taken as a text that redefines subjectivity and identities, elaborates rules and behaviors, and configures meanings and beliefs.

Comparative-Historical Research on Education

The publication of Fritz Ringer's *Education and Society in Modern Europe* (1979) heralded a virtual breakthrough of yet another paradigmatic approach to the field, namely the comparative-historical research on education. Although some forms of cross-national analysis or international account had not completely been missing in previous periods, the programmatic views expressed by Ringer laid claim to new and ambitious objectives: "There is simply no other means of arriving at explanations, and not just descriptions, of change in education than the comparative approach." Substantive research inspired by such views has remarkably increased from the 1970s onward. It covers, for instance, quasi-experimental investigations of the relationships between education and economic growth, large-scale theory-based analyses of the varying processes of educational system formation, as well as cross-national analyses of the emergence and varying discipline formation patterns of education as an academic field of study in the context of European university systems and the emerging social sciences more generally. Comparative-historical research has also shed new light on the role that nation-specific social meanings, widely accepted interpretative schemes, or 'symbolic structures' deeply rooted in a particular civilization have played in shaping distinctive academic cultures and educational institutions (Archer, 1979; Müller et al., 1987; Schriewer et al., 1993).

Not always, however, have attempts at providing convincing explanation through the combination of historical research and cross-national, or cross-civilizational, analysis been successful. Consequently, much debate has been devoted to issues of explanation (*see* Comparative History). While traditionally, and to some extent up to the present, mainstream models of explanation have followed lines of reasoning as defined in the orthodox philosophy of science, far-reaching shifts in both problem awareness and conceptual models have taken place in the wake of recent theory developments (Schriewer, 2000). Among these are, for instance, world-system models and analyses that, by drawing on Braudelian concepts, not only reintroduced a macrohistorical perspective into comparative research, but also tended to replace the latter by analyses of global diffusion processes and of the working of an emerging 'world polity' (Thomas et al., 1987). New forms of reconciling history and comparison are also suggested, however, by insights from historical sociology as well as by interdisciplinary developments discussed under headings such as 'self-organization,' 'morphogenesis,' or 'evolutionary complex systems research' (Gulbenkian Commission, 1996). Thus, comparative-historical research on education informed by concepts and models of this kind seems to be particularly suited, not only to radically historicizing

educational phenomena, but also to linking historical analysis up with insight relevant to social theory.

Abstract

The reality of educational systems and research in Latin America and the Caribbean (LAC) depicts a complex, heterogeneous panorama that includes great disparities across the region and within each country. LAC education greatly differentiates by support from government measured by investment in education, coverage through enrollments, and quality through regional and international tests. When considered these indicators, LAC locates in the mid tier of developing regions in the world. Educational research follows similar patterns. Research quality varies greatly but there are notable improvements, as well as increased production. A handful of countries dominate the scene in production of research in education.

Introduction to Latin American Educational Systems

LAC Educational Systems: Between Complexity and Heterogeneity

Educational systems in Latin America and the Caribbean (LAC) have a longstanding tradition going back to the formation of their nation-states. Education became a default feature of nation-states in LAC, incorporated in their constitutions after independence. In this phase, most educational institutions were public and conceived of as part of the civil service, teachers and principals being public servants and curricular content being determined top-down hierarchically (Schwartzman and Cox, 2010).

Although it is possible to refer to common features of LAC educational systems, the reality depicts a complex, heterogeneous panorama that includes great disparities within the region and within each country measured against most social, economic, and development indicators, including educational measures. LAC education greatly differentiates in support from government measured by the share of Gross Domestic Product (GDP) to education, coverage through enrollments, and quality through regional and international tests.

LAC countries were instrumental in the early development of their educational systems, in giving a priority to primary education in order to educate citizens of the newly formed nation-states. In this sense, in the beginning of the twentieth century, countries such as Argentina increased enrollment rates in primary education to reach a threshold close to universalization of that level. Today, primary education is legally compulsory in all LAC countries. A once elite-oriented secondary education is facing a transformation and various countries are extending compulsory education at least to the lower secondary education level as well. Some countries are advancing in policies toward including preprimary and upper secondary school as compulsory too (SITEAL, 2010). Higher education (university and nonuniversity levels) has already achieved thresholds of massification (defined as enrolling 15% of the age cohort) in most countries and universalization (defined as enrolling 50% of the age cohort) in a few of the countries. Still the region faces challenges related to retention, illiteracy, and overall quality in its educational systems.

Despite the overall regional trends and certain shared features, LAC is a region characterized by enormous differences among countries in terms of educational development. UNESCO's Education for All (EFA) Development Index (EDI) provides a portrait of the status of basic education in that region encompassing four indicators: (1) primary education net enrollment ratio, (2) adult literacy, (3) gender parity and equality, and (4) quality of education calculated as survival rate. In 2007, only six LAC countries ranked 'high' in this global index: Cuba, Argentina, Uruguay, Chile, Mexico, and Venezuela. Fourteen LAC countries ranked in the middle, and one LAC country, Nicaragua, fell into the lowest category of the index. The fact that most LAC countries have only reached a medium level in the EDI composite means that they have not met minimum benchmarks, showing poor levels in adult literacy and quality indicators (e.g., Guatemala) and low retention rates in countries such as Brazil, the Dominican Republic, El Salvador, and Guatemala (UNESCO, 2010).

Another measure of assessment is the allocation of public budget to education. UNESCO and its EFA partners have consistently advocated an increase in the allocation of funding as measured by the share of GDP (4–6%) allotted to education (UNESCO, 2006). Most regions worldwide allocate above 4% of their GDP to education. Only high income countries reach averages close to 6%, including all European Union countries, the United States, and Canada. On average, LAC countries spend 4.75% – just above developing countries in other regions such as Middle East and North Africa (4.69%), East Asia and Pacific (4.44%), and Sub-Saharan Africa (4.33%). South Asian countries lag behind, allocating only 2.85%. This measure also shows great heterogeneity within LAC region. By 2009, 12 countries invested at least 4% of their GDP in education, with countries such as Cuba, Bolivia, Costa Rica, and Argentina investing at least 6% of their GDP. Those countries along with Brazil and Mexico have increased their investments by at least 1.5 points in a decade. However, eight other countries languish with public expenditure in education lower than 4%, with specific cases, such as the Dominican Republic, Guatemala, Uruguay, and Peru, falling below 3% (World Bank, 2009).

Trends and Persistent Issues in LAC Educational Systems

As described earlier, educational systems in LAC region have made progress in certain educational indicators while many issues remain poorly handled and others arise as more complex challenges.

Illiteracy is one of the prevalent issues that educational systems face in the developing world. With 91% adult literacy rates, LAC stands as one of the regions with higher literacy rates than other developing regions, mostly due to proactive policies adopted to reduce the number of illiterates in that region. Only the East Asian and the Pacific region reach 94%, while the Arab States (75%), Sub-Saharan Africa (63%), and South and West Asia (63%) regions lag behind (UNESCO, 2012). Within LAC, the Economic Commission for Latin America and the Caribbean (CEPAL) data on literacy, show that illiteracy is still a prevalent problem in some countries while in others it is reaching eradication thresholds. By 2010, the countries with the highest illiteracy rates in the LAC region were Haiti (48.7%), Guatemala (75.2%), Nicaragua (78%), El Salvador (84.5%), and Honduras (84.8%). Moreover, in countries where literacy rates are low, women are disproportionately under-represented. For instance, in Guatemala, 70.3% of women are literates compared to 80.6% of men (CEPAL, 2012). The Latin American Information System on Educational Trends (SITEAL) reports that in certain countries, differences between urban and rural settings and among regions, are strikingly high when considering illiteracy rates. At the other end of the continuum, 11 countries including Cuba, Chile, Uruguay, Argentina, Costa Rica, and Venezuela show comparatively high literacy rates (SITEAL, 2010). According to UNESCO and the Organization of Ibero-American States (OEI), literacy rates above 95% correspond to eradication of illiteracy. However, it is crucial to highlight that literacy rates are calculated through conventional mechanisms that only reveal extreme cases of illiteracy, and do not include those cases where written and oral language are minimal; thus illiteracy numbers could be higher than those showed in reported databases.

Most regions in the developing world have made sustained progress to incorporating most of their populations in primary education. Net enrollment rates by region show that LAC reached in 2010 95% coverage, similar to East Asia and the Pacific (96%), Central Asia (94%), and South and West Asia (93%) and above Arab States (88%) and Sub-Saharan Africa (77%). However, the regions that already achieved by 1999 percentages over 90%, have not made drastic improvements. Coverage growth in a decade (1999–2010) was only 1% for the LAC region, while there was growth of 18% in South and West Asia and 16% Sub-Saharan Africa during the same decade. This situation may indicate the existence of a glass ceiling in this indicator. Universalization of primary education is one of the earliest achievements of LAC countries. By 2010 net enrollment rates represented a regional average of 95%. Argentina, Ecuador, Uruguay, Cuba, and Panama led with net enrollment rates above 98%. On the other hand, countries such as the Dominican Republic and Paraguay enrolled between 82 and 91% of their potential primary education student population (CEPAL, 2012). In 2011, primary education gross enrollment rates in LAC represented 112.5%, indicating the prevalent efficacy problems (UNESCO Institute for Statistics, 2012).

Since most countries have already reached universality of primary education, issues of quality and efficacy become predominant. Most LAC countries suffer badly from issues related to timely entry, age heterogeneity, and academic achievement. Repetition, the main cause of age heterogeneity, affected mostly primary education. However, progress has been made in most of these areas in the last decades, and the main issues are now found in secondary education (Wolff et al., 2002).

Secondary education is increasingly perceived as the new starting point in educational systems. Overall, LAC region enrollment rates in that level reach 73.5%, being below developing countries in Europe and Central Asia (82.5%) and ahead of East Asia and Pacific (72%), Middle East and North Africa (68%), and Sub-Saharan Africa (26%) (Latest data available 2007) (World Bank, 2010). Within LAC, most countries extend compulsory education to, at least, the lower secondary level. This aim represents a challenge for a level of the educational systems that was conceived to educate the elites of LAC countries and prepare them to continue studies in higher education institutions. In 2010 net enrollments rates for secondary education in LAC countries averaged 73.5%, ranging from the lower end with enrollments between 45 to 63% in countries such as Nicaragua, Guatemala, El Salvador, Paraguay, and the Dominican Republic to the upper-end with net enrollments between 84 to 86% in countries led by Cuba, Bolivia, Chile, and Argentina (CEPAL, 2012). By 2010, gross enrollment rates in LAC countries represented, in average, 90% – a difference revealing efficacy issues.

Efficacy issues in secondary education translate into inequality in secondary level completion rates. This disproportionately affects populations in the lower end of the socio-economic scale: students who do not enter the secondary education level and those leaving secondary education before obtaining the degree. In countries such as Guatemala, Colombia, and Honduras completion rates are highly unequal when considered by quintiles. In contrast, countries such as Chile and to a lesser extent Peru and Argentina, show higher completion rates and lesser inequalities in secondary education. Overall, in LAC the ratio of high-SES (socio-economic status) students graduating from the secondary level is three times higher than the number of low-SES students completing that educational level (CINDA, 2011).

Current trends in secondary education enrollments may signal the existence of a ceiling that impedes universalization of that level. It is expected that limitations on the growth of enrollment rates in LAC countries will affect more seriously those who benefited the most from the universalization of primary education: indigenous populations, African descendants, low-SES adolescents, and people living in rural areas (López, 2013).

LAC region has been involved in a series of educational reforms starting in the 1980s to adapt the systems to new realities. Educational reforms in primary and secondary education have ushered in several changes. One of them relates to changes in the structure of educational systems based on the incorporation of more years of compulsory schooling and taking into account psychological principles on developmental stages. A second type of change relates to curricular reforms that tend to transition from a discipline-based curriculum to an area/integrated-type of curriculum. A third innovation has impacted the management and governance of educational institutions through increasing decentralization and autonomy, outcome assessment, and resources allotted on a competitive basis (Tedesco and López, 2004).

Trends and issues found in the other levels of education are largely echoed when it comes to higher education. In comparison to other regions, LAC positions itself in a similar standing as in primary and secondary education enrollments. Developing countries in Europe and Central Asia lead the scene enrolling 56% of their age grade group, followed by LAC (41%), Middle East and North Africa (30%), and East Asia and Pacific (26%). South Asia (15%) and Sub-Saharan Africa (7%) locate at the bottom of the continuum. As in most educational indicators, the gap between developed and developing nations is striking. High income OECD-member countries, in average, enroll 75% of the age grade group in higher education.

Within LAC, as of 2010, with more than 6.5 million students enrolled in higher education, Brazil has easily the largest higher education system, followed by almost 3 million students in Mexico and 2.5 million in Argentina (PROPHE, forthcoming). In the age grade group enrolled in institutions of higher education (18–24 years), five higher education systems in the LAC region enroll at least 50% of the age grade group, thus reaching the universality threshold set by Trow's typology (1973): Cuba (95%), Venezuela (78%), Argentina (75%), Chile (66%), and Uruguay (63%). Most of the other LAC higher education systems enroll between 15% and 50% of the age grade group, including the two largest higher education systems in the region, Mexico (28%) and Brazil (26%) (World Bank, 2010).

Most of the issues faced by LAC higher education systems relate to their foundations. Systems were originally designed to train the political elite. In general, the establishment of universities in the colonial period followed a model that privileged the training of professionals, focusing the functions of the institutions on teaching activities rather than research. The roots of the emphasis on professions can be traced back to the Napoleonic (French) model. That model based institutional efforts toward the development of professional fields of study at the undergraduate level, such as law and medicine. Thus, research was rarely a preeminent activity in the early days of universities in LAC (Brunner, 1990).

To a greater or lesser extent, massification and universalization brought issues related to effectiveness, quality, autonomy, and efficiency to the forefront (Castro and Levy, 2000). LAC higher education systems are attempting to increase the number of minority and low-SES students accessing and completing higher education. However, they still face structural issues such as low graduation rates. Higher education systems in LAC are highly ineffective, graduating a small proportion of those entering the level, and also inefficient since those graduating may spend as twice as much time, than the time scheduled to finish their studies. To tackle quality issues, reforms have focused on the establishment of quality assurance processes through accreditation agencies. Today, most countries in LAC have implemented some type of accreditation system, for institutions and programs.

From Quantity to Quality: Educational Assessments in LAC

Although educational coverage indicators are still used as a proxy to measure educational systems' progress, increasingly international organizations and governments are utilizing indicators of quality. During the 1980s and 1990s, most LAC countries developed their technical capabilities and established or improved their systems designed for measuring and assessing student academic performance mostly through two different modalities: indigenous creation of tests for highly specific purposes, such as those utilized to regulate admission to higher education or those created with support provided by international financial agencies such as the Inter-American Development Bank (IADB) and the World Bank (Ferrer, 2006). The status of educational assessments in LAC tends to vary significantly by country. Countries such as Chile and Colombia have long experience in administering tests with a high degree of legitimacy and continuity, while other systems in place in countries such as Bolivia, Ecuador, Guatemala, and Peru have been subjected to political changes, making data more difficult to be publicly accessed, with abrupt changes in technical staff (Ferrer, 2006).

LAC countries are increasingly participating in regional and international educational tests, such as the Trends in International Mathematics and Science Study (TIMSS), the Program for International Student Assessment (PISA), and the Regional and Comparative Regional Study (ERCE). Around 20 countries have administered at least one comparative international assessment (Ferrer, 2006). One of the main proxies to assess the comparative quality level of educational systems worldwide is the PISA assessment designed and administered by the Organization for Economic Co-operation and Development (OECD). More than half of the participating countries are highly developed ones. Various Latin American countries such as Chile, Uruguay, Mexico, Colombia, Brazil, Argentina, Panama, and Peru have participated in different years in the administration of the international test, which measures competences developed by 15 year-old students in reading, mathematics, and science. As expected by the large number of OECD-member/developed countries included in the test, LAC countries performed below the OECD average in every competency measure, ranking in the bottom third section out of 65 developed and developing countries. Measurements also show major performance differences within countries, indicating striking gaps between those students in different quintiles of the population (OECD, 2010).

Besides the international assessments described earlier, different regions in the world have developed their own assessment regimes. In LAC, ERCE is a comparative assessment of primary education students in their third and sixth grades that tests their knowledge in mathematics, language (reading and writing), and natural sciences. The different stages of ERCE tests have been designed by the Latin American Laboratory for Assessment of the Quality of Education (LLECE), an initiative that promotes regional tests and is coordinated by the Regional Bureau for Education in Latin America Latina and the Caribbean (OREALC-UNESCO) branch in Chile. Implemented for the first time in 1997, the test is the oldest initiative of this nature in the LAC region. The SERCE test or Second ERCE administered in 2006 shows relevant differences in the performance of students in different LAC countries. Cuba is the single country reaching mean scores significantly higher than the regional average in mathematics (3rd and 6th grades), reading (3rd grade), and natural sciences (6th grade). A second group of countries with identical and higher scores than the regional average are Argentina, Brazil, Chile, Colombia, Costa Rica, Mexico, and Uruguay. Finally, a third group exhibits mean

scores lower than the regional average: Guatemala, Ecuador, El Salvador, Nicaragua, Panama, Paraguay, Peru, and the Dominican Republic (LLECE, 2008).

Although LAC countries have been increasingly willing to participate in regional and international educational assessments, information exchange between assessment entities and system users remains weak. Connections are also missing between test results and policies/decisions and this is related to the limited involvement of the major educational stakeholders (policymakers, teachers, principals, parents, etc.) in devising the tests, designing the reports, and defining strategies for dissemination (Ferrer, 2006).

Educational Research in and About LAC

Investment in R&D in the Region and Educational Research Indicators

Educational research in LAC is part of a broader context of development and investment in Research and Development (R&D) patterns worldwide. When compared to other regions, LAC expenditure in R&D in 2010 locates in the fourth place with 3% of the worldwide expenditures in that sector, behind Asia (34.1%), North America (United States and Canada) (33.1%), and Europe (26.9%) and just ahead of Oceania (2%), and Africa (0.8%) (RICYT, 2012). These patterns reflect structural limitations to research productivity in the LAC region that may impact on educational research, which is part of it.

As described in the previous section, LAC is a region characterized by a great internal heterogeneity that makes difficult to generalize on the status of educational research in the region. Data shows that three LAC countries dominate the R&D scene, investing more than 90% of the R&D resources. By 2010, Brazil led the list with 63.3% of the total investment in R&D in the region, followed by Mexico (19.2%), and Argentina (9.7%). The other LAC countries count just for the remaining 7.8% (RICYT, 2012). These shares can be seen in educational research productivity, where Brazil and Mexico are the key players in the area.

One of the most evident differences between countries within the LAC region relates to research productivity measured through human resources and bibliometric indices. The consolidation of the R&D systems as well as Science and Technology (S&T) statistics systems are appropriate proxies. R&D systems include number of university graduates as percentage of population and the number of publications in international databases. The application of R&D measurements generates three categories when applied to LAC countries (Arber et al., 2008): (1) A first group of countries with consolidated R&D and S&T statistics systems includes Argentina, Brazil, Mexico, and Chile; (2) A second group with consolidated R&D and less developed S&T statistical systems includes Colombia, Costa Rica, Cuba, Panama, Uruguay, and Venezuela; finally, a third group with R&D and S&T systems in early developmental stages embraces Nicaragua, Peru, El Salvador, Paraguay, Guatemala, Bolivia, Ecuador, Dominican Republic, and Honduras.

To a certain extent, S&T statistic systems reflect the overall availability and collection of educational data in LAC countries. Quality and availability of educational data has broad implications and may impact educational research. Some countries in that region are advancing their data generation, collection, and publication mechanisms, and one of the most relevant cases is Brazil. The *Microdados* a web-based, public, and free-access secondary database reported by the Institute of Educational Statistics (INEP) in Brazil makes available disaggregated educational data on primary, secondary, and higher education indicators, educational assessments, and research conducted by INEP from 1995 onward. Raw and non-identifiable data is made available in databases ready to be inputted in quantitative analysis software. This represents a step forward in LAC countries, where the traditional and still predominant method to show data on educational systems consists of reports which show already processed data. Developments on data availability in LAC have usually been promoted by international funding agencies through their loan systems, to develop capacity through training of technical staff and the establishment of entire subunits within educational bureaus at the national and state/provincial levels.

As described, educational research follows patterns similar to those already existing in R&D indicators overall. A handful of countries dominate the scene on production of research in education. A useful although not comprehensive proxy to assess educational research productivity refers to the availability of peer-reviewed academic journals. In recent decades, there have been a series of initiatives to generate digital catalogs of peer-reviewed journals available in LAC such as Latindex and Scielo. The UNAM-based Latindex is conceived as the largest LAC journal index system and compiles almost 5000 scientific journals in that region of which almost 1200 correspond to education journals. Brazil leads the number of educational journals indexed by Latindex with a total of 377 journals, followed by Mexico (167), Chile (144), Venezuela (47), and Colombia (47). Latindex fixes common standards in international journal publications, only including those that meet minimum criteria, so the real number of journals in each country may double or triple those in indexed databases. Still, there is a pattern toward the incorporation of greater number of journals to be included in indexes since they raise their legitimacy and visibility.

All the journals indexed in Latindex as well as Scielo and other regional databases are published either in Spanish or Portuguese; thus limiting visibility outside the region. Journals have usually been published only in hardcopy versions limiting the accessibility and dissemination of LAC educational research. This situation is progressively changing, and journals that were available only in hardcopy are turning to digital versions. This trend shows a turn from local communities of researchers to more cosmopolitan research communities, at least at a regional level.

Research Traditions in Education

Tracing back, beginning in the 1950s and 1960s, educational research in LAC countries was greatly influenced by the human capital theory. The main assumption surrounding educational research was the idea that educational systems would act as the main drivers of change in overall society. For instance, secondary education was portrayed as an agency for economic development and most official documents accepted the existence of a relationship between increasing the number of secondary graduates and economic progress (Watson, 1967).

Not only research but also policy making developed in this stream considered education as a major institution to shape overall development. This shared paradigm on educational research and policy was coupled with studies on the universalization of compulsory education and the struggles to turn a once elite secondary level into a mass/universal level.

Coupled with human capital theory, Durkheim and its structural-functionalist approach in sociology influenced educational researchers and their understanding that quality of education could be assimilated to enrollment rates, and the possibilities of fulfilling the functions of educational systems. In education this era was characterized as 'pedagogical optimism.' In other words, both society and researchers deposited trust in the transformative effects of education and its role in promoting development.

Within the first tradition, educational research was in its first stage, characterized by a more descriptive and normative approach corresponding to an underdevelopment of the social sciences and of their research methodologies. Researchers outside the region were producing sound research about LAC but its impact in the region was minimal at that time (Watson, 1967).

Mostly starting in the 1970s and 1980s, critical theories in education began to criticize the idea that education could be a predominant way to change society, allowing for social and economic mobility. Based on sociological literature such as that produced by Bourdieu and Passeron (1977), and Baudelot and Establet (1971), researchers fell in what is known as the 'pedagogical pessimism.' In other words, researchers focused on what seemed to be reproductive functions of education rather than transformative ones. According to these theoretical developments, educational systems would be responsible for maintaining social inequalities in societies, and even legitimize them rather than promote upward mobility and social change. Moreover, according to Marxist approaches to education, schools were seen as agencies of the dominant (capitalist) ideology that served the interest of the ruling class.

The 1980s and 1990s came accompanied with the restoration of democratic governments in LAC and most countries began to discuss possible ways to overhaul their educational systems. In this period, international funding agencies such as the World Bank and IADB, acted as the main funding agencies for those reforms across Latin America, promoting the dissemination of ideas that had the focus on the decentralization and privatization of educational systems. The development of these trends pushed the research agenda toward the study of educational systems in LAC in terms of policy, governance, structure, curriculum, and teacher professionalization. These developments were understood as part of a neoliberal agenda in a scenario guided by the Washington Consensus.

The 1990s reforms brought new developments to educational systems in LAC from primary to higher education, such as decentralization, new teaching and research conditions (e.g., merit-pay systems), new curriculum developments, overall quality assurance processes, and governance systems. During this period, research began to analyze the so-called NPM-based (New Public Management-based) reforms aimed to generate more efficiency and promote quality in the public sector through practices already consolidated in the private sector. This movement toward policies oriented by deregulation, regulation, and liberalization of education systems takes place in a broader context of discussion on public and private educational services, and its incorporation in the WTO's (World Trade Organization) GATS (General Agreement on Trade in Services) as a tradable commodity. These policies have been usually labeled as neoliberal policies and researchers have adopted a critical stance against the introduction of market-based policies in the educational sector.

Research focusing on policy analysis from different social sciences (political science, sociology, anthropology, and economics) has dominated educational research in LAC countries in the last decades. Research results published in academic journals in between 1993 and 2001 show the dynamic change in educational research theoretical and epistemological paradigms described earlier. In the last decades researchers studying educational policy have predominantly used three main epistemological approaches: neo-Marxism, poststructuralism, and pluralism. A small number of published articles in LAC journals utilize structural-functionalist approaches (Tello and Mainardes, 2012).

First, the neo-Marxist perspective allowed for relative autonomy and individual agency on the relationship between schools and capitalist relations of production that Marxist theory already claimed more recently, studies on educational policy in Latin America have followed Dale's (2000) neo-Marxist approach. Second, educational studies in Europe and the United States (Ball, 1994; Popkewitz and Fendler, 1999) triggered the adoption of poststructuralist perspectives in Latin America, based on the idea that actors occupy a central role in the understanding of policies and that power flows among multiple and different actors. Finally, the pluralist approach focuses on the understanding of diverse interpretations about an educational policy issue (Tello and Mainardes, 2012). All of these perspectives reject the possibility of understanding education as an objective reality, in clear opposition to positivist approaches.

Another characteristic of educational research in LAC countries is its focus on local developments directed toward a local community of researchers. Only in recent decades, and through the expansion of societies on comparative and international studies, researchers are showing more interest in generating comparative research at regional and international level. Comparative education societies in Argentina (2001), Brazil (1983), Cuba (1989), Mexico (2003), and the recently created in Uruguay (2009) promote the production and dissemination of comparative research through the organization of conferences and the publication of specialized peer-reviewed journals.

Latin American studies centers and associations are active in most developed countries. The US-based Latin American Studies Association (LASA) is one of the main Latin American studies association worldwide and the largest in the United States with over 8000 members. Their annual conference papers reflect, to a certain extent, the visibility of educational research in Latin American studies in the United States. The largest comparative educational society, the United States-based Comparative and International Education Society (CIES) also attracts scholars who study educational systems in LAC countries.

The assessment of educational articles in Latinamericanist journals may signal that educational researchers are not the mainstream of Latinamericanist studies and that educational scholars may choose other publication outlets, usually

discipline-based journals. For instance, although not a Latinamericanist journal, the US-based Educational Policy Analysis Archives (EPAA) journal publishes educational policy papers in English, Spanish, and Portuguese reaching academics in the United States and the LAC region, thus generating a hybrid between American scholars studying LAC educational issues and their counterparts from the scholarly community in LAC.

Educational Research by Level

Research on primary and secondary education is mainstream with scholars in LAC, although it is hardly a distinctive feature of the region, since most educational research is oriented to the study of those educational levels worldwide. National associations of researchers in education are increasing in number but are still a rarity in the region. Crucial exceptions are the Brazilian National Association of Educational Research (ANPED) and the Mexican Council on Educational Research (COMIE), dating back to 1976 and 1993, respectively. Countries such as Argentina have not developed yet an overarching research community in education through a generalized affiliating association/society. Instead, they have developed discipline-based associations. For instance, in Argentina societies are established on the bases of specific topics and issues or in the study of education from specific social sciences, e.g., SAHE, the Argentine society for the study of the history of education.

As described in the previous section, educational issues in LAC transitioned from enrollment rates in primary and secondary education to what nowadays is predominantly a concern related to quality and its relationship to equity, stratification, and social mobility. Studies are increasingly centering the analysis of education in LAC countries on how students are performing and the implications that different levels of quality within countries affect educational systems and generate concerns on social equity (Schwartzman and Cox, 2010).

Nonformal education related to education of (illiterate) adults as well as educational issues in rural areas has usually been overlooked by traditional research. The UNESCO center for the study of adult education, CREFAL, has been instrumental in the development of research through specific funding and training of doctoral students and researchers in issues on nonformal education. Founded in 1950, the center produces reports and disseminates research with a focus on the research-action perspective.

Research on higher education is still in a developing stage in LAC, mostly when compared to theoretical and methodological developments in Europe and the United States. Most publications produced in that region have a strong normative, propositional, and ideological content although that situation is changing over time due to new developments and more researchers trained for research in this specific level of education (Krotsch, 2001). Research on higher education began to change its focus and ways of approaching issues starting from the 1980s in concomitance with the growth of public and private universities and their competition for students, professors, and ultimately for prestige. Public policies oriented to report information on higher education systems; international organizations and foundations in charge of financing educational research; and the emergence of graduate level and the issues linked to management and teaching derived from a new sublevel (Krotsch, 2001).

Three different traditions have permeated the study of higher education in LAC. Durkheim's functionalist perspective, mostly utilized in the study of the higher education systems in the region following similar analysis to those carried out by Durkheim on the historical development of higher education in Europe in the medieval times. Bourdieu's analysis of fields in order to uncover their principles of social regulations and reproduction. Finally, and most importantly the sociological studies of educational systems in comparative perspective elaborated by Clark (Krotsch, 2001). The developments from the latter are still the most widely utilized frameworks for the analysis of higher education systems in LAC, based on the idea of a coordination triangle between the state, the market, and the academic oligarchy.

The single most proactive research community in developing research on higher education issues in LAC is Mexican encompassing the UNAM's Center for the Study of Higher Education (CESU) now called Institute for the Study of University and Education (IISUE) one of the most longstanding and prestigious research centers producing research in that level. UNAM also created the Higher Education Researchers Network (RISEU), a network of Latin American higher education scholars that promotes the dissemination of research in that specific level. The North American country also counts with specific higher education research centers in the Montemorelos University (UM), the Center for Research and Advanced Studies (CINVESTAV) of the National Polytechnic Institute (IPN). The Ibero-American University (UI), a private Jesuit university also created its own and well known research center on higher education.

Brazil has consolidated various centers on the study of higher education recently. The longstanding Higher Education Research Center (NUPES) now called Public Policy Research Center (NUPP) at University of Sao Paulo, and many others in the public and the private sector (*Observatorio Universitario*) play a critical role in the production of knowledge specific for this level of education. In Chile, the Latin American School of Social Sciences (FLACSO) and a group of centers specializing in the study of higher education such as the Development University Center (CINDA) and the Corporation of University Promotion (CPU) not only produce research targeted to scholars and also policy makers. In recent years, CINDA has been at the forefront of regional comparisons of higher education systems in the LAC region.

The Regional Center for Higher Education in Latin American and the Caribbean (CRESALC) later renamed as the International Institute for Higher Education in Latin America and the Caribbean (IESALC) is another relevant institution in the promotion of the study of higher education in LAC. An UNESCO institution in Venezuela, CRESALC was first established in 1978 with the aim of contributing to the cooperation and improvement of higher education systems in the region. Now, IESALC serves as a hub to promote the development of national reports on higher education systems, as well as comparative studies, and in certain cases, the compilation of statistics.

International funding agencies also played a key role in the dissemination of knowledge on higher education systems in LAC. In its own review of higher education policies to promote educational reform, the World Bank edited reports on LAC higher education systems: *Higher Education: The Lessons of Experience* published in 1994 and *Higher Education in*

DevelopingCountries: Peril and Promise edited in 2000. The IADB also published the report *Myth, Reality, and Reform: Higher Education Policy in Latin America* by two Latin American experts in higher education. To a greater or lesser extent, these reports called for an overhaul of the higher education systems, based on the conviction that institutions of higher education in that region were highly ineffective and inefficient, and necessarily required organizational and structural change and diversification. These reports brought research concerns into the educational agenda, mostly from the United States, that were absent or overlooked by researchers in the region and generated controversies. Those reports emphasized certain discussions on autonomy, financing, and evaluation, from a perspective of equality of opportunity that did not fit the still predominant LAC approach of a highly state subsidized higher education system with highly autonomous institutions.

Policy recommendations emanating from international funding agencies' reports, specifically those produced by the World Bank, generated widely divergent reactions from two sectors in the higher education research community. One view considered the reports as part of a neoliberal agenda in educational reform overall that tended to highlight alternative approaches to higher education finance, autonomy, and governance. Another sector of researchers were promoting comparative studies of higher education systems and assessing the limitations of the 'Latin American model' of autonomy and governance.

Heterogeneity and unimpressive quality signal the current status of LAC educational systems and educational research. Enormous disparities exist with a few countries consistently outperforming on different educational indicators, the majority with mediocre performances. When compared to other regions in the world, this highly heterogeneous situation leads LAC to remain located below Central Europe and East Asia and above South Asia and Sub-Saharan Africa.

Education in Psychiatry

Brian Lunn, School of Medical Education, The Medical School, Newcastle University, Newcastle upon Tyne, UK

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by H.J. Walton, volume 6, pp. 4227–4234, © 2001, Elsevier Ltd.

Abstract

Medical education has been leading the way with rapidly evolving pedagogic methodologies. While psychiatric education has been slightly behind the curve this evolution has made significant changes to teaching and assessment of the subject in recent years. Curricula are evolving and being exported. An evidence base is informing practice. There has been a shift to emphasizing measurable variables such as reliability in assessment. Regulators are taking increasing interest in the output of both undergraduate and post graduate training programs. This comes with a risk that the rush to standardization and reliability will result in increasing homogenization and loss of validity.

Introduction

In the previous edition of this article Walton (2001) highlighted the 'creative ferment' that was the state of medical education worldwide. The intervening years have done nothing to decrease this ferment. What has developed is an increasing focus on measurable variables, standardization, and regulatory control.

What has been true for medical education in general is reflected in psychiatry but it would appear that in some respects we have been behind the curve (Gask et al., 2011). In many parts of the world a traditional knowledge base, apprenticeship model still dominates while in others rapidly evolving pedagogic methodologies are leading to a disparity of approach.

Many universities across the world still rely on traditional curricula with divisions into preclinical and clinical phases but there has been an increasing shift to curricula that integrate these elements. Such curricula can be 'blended'; with a mix of didactic lectures and various small group formats, or 'problem based.' Alongside this shift of undergraduate pedagogy has been a shift in teaching in postgraduate environments and specialty training.

With a growing realization that the separation of medical training into undergraduate, general post-qualification, and specialty training was impacting adversely on recruitment into psychiatry, there has been a drive in some countries to introduce psychiatric posts much earlier in training. This development has been alongside bodies such as the Royal College of Psychiatrists putting emphasis on developing curricula that allow for integration of psychiatry early in undergraduate courses (Royal College of Psychiatrists. Report of the Royal College of Psychiatrists' Scoping Group on Undergraduate Education in Psychiatry, 2009).

Curriculum Development

Undergraduate

As highlighted above in some areas of the world traditional curricula as described by Walton (2001) remain the norm, but the trend internationally has been to see a shift from curricula being set by their academic clinicians to being designed by educationalists with an eye to research evidence. The biggest change is to base teaching around how patients present. For psychiatry this means that students are introduced to how patients with mental health problems present at an early stage of their course. The focus has also shifted to what the pluripotential doctor needs to know rather than aiming at protospecialists. That 'physical' health problems such as ischemic heart disease may coexist with mental health problems reflects the reality of clinical practice and directs learning that is focused on understanding a patient in the context of their physical, social, and psychological/psychiatric well-being.

General Post-Qualification Training

Most doctors on qualifying proceed then to 1 or 2 years of general training that may or may not include psychiatry. The international concern about recruitment into psychiatry (covered in more detail below) has led to calls for psychiatry jobs to be made available or integrated into this period of training at as an early stage as possible. That the focus of such early jobs should be training rather than service delivery has gained greater traction recently as has the awareness that a broad base of clinical experience cannot only improve recruitment into low uptake specialisms but improve quality of care for patients.

Specialty Training

The duration of specialty training in Europe averages 5 years (Mihai, 2006) but content and approach vary significantly (**Figure 1**).

Quality assurance of training, when those who deliver it are often widely distributed and not always fully engaged with governing bodies, can be challenging. European Union legislation and the European Board of Psychiatry (Hohagen, 1996) require that national authorities own national quality assurance of training and are responsible for establishing training programs. The European Federation of Psychiatric Trainees (EFPT) have also set out their recommendations for inspection of training. These elements include working conditions and all clinical and academic aspects (European Union of Medical Specialists Report of the European Board of Psychiatry – Quality Assurance in Specialist Training in Psychiatry, 2002). Key to their effectiveness was felt to be the ability to insist on changes to be made or, where appropriate removal of approval from training posts or schemes.

Figure 1 Length of training in psychiatry in Europe.

Training elements considered by quality assurance teams
Accessibility to clinical supervision
Individual supervision
Supervision in psychotherapy
The qualification of trainer
Number of trainees allocated to one supervisor
Structure of theoretical courses
Cases presentation opportunities
Problem solving cases
Workload
Numbers of duty hours
Number of patients examined by each trainee per day
Presence of a trainees' room and a consultation room

Reproduced from European Union of Medical Specialists Report of the European Board of Psychiatry – Quality Assurance in Specialist Training in Psychiatry, 2002.

A common core of knowledge and skills was specified by the European Board of Psychiatry who recommended that this be required of all trainees (European Union of Medical Specialists Report of the European Board of Psychiatry – Quality assurance in specialist training in psychiatry, 2002).

Compulsory training in various settings:
Inpatient units
Outpatient/community settings
Liaison
Emergency psychiatric settings (e.g., emergency departments and police stations)
Compulsory specialisms:
General adult psychiatry
Old age psychiatry
Psychiatric aspects of substance misuse
Psychotherapy (as a minimum psychodynamic and cognitive/behavioral models)
Highly recommended specialisms:
Developmental psychiatry
Forensic psychiatry

Reproduced from European Union of Medical Specialists Report of the European Board of Psychiatry – Quality Assurance in Specialist Training in Psychiatry, 2002.

Training should include structured training (lectures, seminars, and so on) over 4 years for, on average, 4 hours per week.

Subjects core to training
Scientific basis of psychiatry: biological, social, and psychological aspects
Psychopathology. Examination of the psychiatric patient. Diagnosis and classification. Psychological tests and laboratory investigations
Specific disorders and syndromes
Psychotherapies. Psychopharmacology and other biological treatments. Multidimensional clinical management. Community psychiatry
Child and adolescent psychiatry. Mental handicap. Psychiatric aspects of substance misuse. Old age psychiatry. Women and psychiatry. Psychiatry of ethnic minorities. Legal and ethic issues in psychiatry
Research methodology. Epidemiology of mental disorders. Psychiatric aspects of public health and prevention
Medical informatics and telemedicine. Administration, management and economics

Reproduced from van Diest, R., van Dalen, J., Bak, M., et al., 2004. Growth of knowledge in psychiatry and behavioural sciences in a problem-based learning curriculum. Medical Education 38, 1295–1301.

(*Continued*)

Training in psychotherapy was seen as vital and on a par with biological and social elements. This was felt to enhance the ability of psychiatrists to understand and provide balanced treatment for their patients. The key is, as with other treatment modalities, to use methodologies based on scientifically proven systems and the available evidence base.

Whether due to marketing of curricula as western universities move to a business model or in the hope of developing an internationally mobile workforce, there has been a drive to export/import curricula. This is not without its own problems. Typically the direction of movement is from West to East but this is not with any evidence to say that western models work in eastern countries (Bleakley et al., 2011; Rao, 2006a,b). Of some possible concern is that any failure of such transplantation leads to the assumption that this reflects problems with the local society reflected by the "apologetic stance taken by authors in the east about their slowness in adopting western methods, even though … those methods will demand 'intense re-socialisation of learners into metropolitan Western mindsets'" (Bleakley et al., 2011: p. 177).

In addressing this Grant (2014) has argued that "we should be clear about the necessary components of a curriculum designed to be sensitive to the local context." She suggests that this requires consideration of those aspects of the skill and knowledge set required for clinical practice in that locale. Teaching needs to reflect local clinical priorities, the practice setting including how services are provided, how patients present with problems and how cultural factors affect communication and decision making.

In western countries regulators such as the General Medical Council (GMC) in defining their curriculum requirements not only list the learning outcomes they require medical schools to teach but also that quality assurance and stakeholder engagement be factored in (General Medical Council, Tomorrows' Doctors, 2009). They follow up on this with periodic visits.

All of this has led to a shift to defining the purpose and context of a curriculum from content. This could not have been more starkly highlighted than when a post-qualification training reorganization (Modernizing Medical Careers in the UK) required almost immediate post implementation review that reasserted the importance of the apprenticeship model (Took, 2008).

Patient Involvement

The role of patients in medical student teaching has waxed and waned over the millennia (Rosher, 1997). To an outsider in the twenty-first century it must seem incredible that patients would not be front and center in medical education yet there was a significant period when this was not the case and it was only gradually that the patient returned. Even then, while medicine has emphasized teaching at the patient's bedside for many centuries now, the patient "was often no more than a medium, 'an interesting case'" (Spencer and McKimm, 2014).

In the latter half of the twentieth century there was an intense debate as to the nomenclature to be used to describe those with whom doctors came into contact with in the line of duty; patients, clients, service users, or consumers? Often this debate focused on the power dynamic and was driven by vocal activists yet an unexpected benefit was that it usefully highlighted the involvement of patients (for simplicity the most widely and commonly used term is used here) in educating students.

Spencer et al. (2000) in their review of roles that patients hold in medical education suggested a framework for involvement based around four contexts as follows:

- Why (… the patient's background, culture, experience and education enhanced learning)?
- How (… patients may be involved)?
- Where (… to involve patients)?
- What (… to involve patients in)?

One challenge is how to involve patients education beyond the bedside (e.g., assessment policy) while ensuring that this is not mere tokenism. One problem with the term 'patient' is that it implies active illness, when in reality we may all become (or have been) patients. It is therefore possible to have 'patient' involvement in the most technical aspects of medical education by involving people with particular expertise (the 'Why?' suggested by Spencer et al. above) who are not involved in health care. Particular examples of this can be seen in the involvement of nonmedical academics from the humanities with expertise in assessment pedagogy in quality assurance of assessment as is the case with the Royal College of Psychiatrists and Newcastle University.

In psychiatry there can be particular issues around the capacity of patients to consent to involvement in teaching when they are at their most unwell. One solution is the use of simulated patients. Well trained simulated patients can, for medical students and trainees, be difficult to distinguish from 'real' patients (Kurtz et al., 2005; Thistlethwaite and Ridgeway, 2006). The quality of training and support for simulated patients is of particular importance in teaching in psychiatry due to the potential harm when playing roles that are emotionally intense (Eagles et al., 2007) but with training and support the benefits have been argued to outweigh potential disadvantages (Spencer and Dales, 2006).

Selection

For those wishing to become psychiatrist there are many selection hurdles to get over. In the UK this includes as a minimum:

- selection to medical school
- allocation to a foundation training program
- acceptance into core specialty training
- appointment to a higher specialty training post
- appointment to a consultant post

These various selection processes use a heterogeneous group of processes and tools with some part of national programs and some very local.

Traditionally the approach to undergraduate selection has focused on high academic achievement with the emphasis on science-based subjects. In some areas the humanities are totally disregarded when considering academic performance for selection. What is changing is a shift to personal characteristics. One example would be that seen in the UK where there is a multiplicity of approaches across medical schools. Common

to all is that via a centrally administered university application process candidates need to demonstrate that they have achieved an academic threshold (or are expected to do so). From there different universities use personal statements, references, aptitude tests, and interview to varying degrees.

The use of aptitude tests varies from country to country and even when the same test is used in a country how it is used between institutions may vary.

Admission aptitude tests	
Test	*Countries using test*
United Kingdom Clinical Aptitude Test (UKCAT)	United Kingdom
Medical College Admission Test (MCAT)	United States of America and Canada
Graduate Australian Medical School Admission Test (GAMSAT)	Australia and Ireland
Undergraduate Medical and Health Sciences Admission Test (UMAT)	Australia and New Zealand

The use of such tests is only relatively recent so there is, on the whole, little in the way of published evidence about their validity. Data from studies of the MCAT (Tutton and Price, 2002) and UKCAT (Wright and Bradley, 2010; Sartania et al., 2014) provide some support for their use but it has been questioned whether these provide any more useful data than traditional educational assessment (McManus et al., 2005).

Use of interviews to select has become a focus for argument, not least because of the inherent subjectivity. As a result the Multiple Mini Interview (MMI) has begun to be used in selection. Developed at McMaster University in Canada from 2001, it proved to be a reliable predictor of future performance (Eva et al., 2004). In a typical MMI each candidate rotates through the circuit of interviews, with one interviewer per station in that circuit. The interview stations focus a variety of objectives required by the selecting institution. Examples of domains include ethics, professionalism, interpersonal relationships, working with others (e.g., managing people, communication, and collaborating), as well as task performance. A common number of stations is around nine or more, each of about 8 min.

Again selection to initial post-qualification varies significantly throughout the world (Crane and Ferraro, 2000). In most areas of the world traditional interviews will hold sway but there is a push to use more objective methods. In the US the National Resident Matching Program (NRMP) (Miller et al., 2003) gives the United States Medical Licensing Examination (USMLE) primary importance. In the UK a program has been put into place that feeds through from leaving medical school to selection for specialty training in areas such as psychiatry. For selection into Foundation Program jobs all graduates are ranked nationally based on performance at medical school. A wide variety of metrics are used in this ranking process. Before submitting their application all candidates take a Situation Judgment Test (SJT) (Patterson et al., 2012; McDaniel et al., 2001). From this, jobs are allocated based on the candidates' preference for area of the country and type of program.

After 2 years of Foundation training selection to core specialty training in psychiatry is from a national process using selection centers. First used by the military in World War II such selection centers were adopted by industry and then pioneered in the UK for family practitioner selection (Patterson et al., 2001, 2005) before being picked up by other specialisms, including psychiatry. In 2014, for the first time, Higher Education England piloted a Specialty Selection Test (SST) for application to specialty posts, including psychiatry. This pilot test included a Clinical Problem Solving Test (CPS) and an SJT. The results of this test are awaited (Higher Education England. Specialty Selection Test (SST) pilot study for first year applicants to specialty and core training).

Recruitment into Psychiatry

Recruitment into psychiatry is an issue that has been recognized internationally (Pidd, 2003; Feifel et al., 1999; Malhi et al., 2003; Strebel et al., 2000; Fazel and Ebmeier, 2009; Bulbena et al., 2005). In the UK the Royal College of Psychiatrists' annual census has regularly shown that 10-15% of consultant posts are vacant alongside medical student interest in a career in psychiatry resting around 4-5%. Over the years the changes in the demographics of those entering medical courses has had no effect on these figures. Neither have changes in undergraduate curricula. This may be, in part, due to the stability of selection criteria with primacy of sciences over humanities (Brockington and Mumford, 2002) and in some medical schools that physics and chemistry are rated more highly than biology. Silvermann et al. (1983) in a study showed that medical students in Boston were unlikely to consider psychosocial factors in the presentations of patients with chest or abdominal pain and posited that it may actually be that medical curricula reinforce a bias toward such an approach.

A study looking at doctors in the post-qualification training period identified three broad areas that appeared to impact positively on choice of psychiatry as a career (Shah et al., 2011). These were early medical school experience, the influence of more senior doctors, and various aspects related to the working environment.

Shah et al. were not unique in identifying the first of these items (Brown et al., 2007; Baxter et al., 2001; Holm-Petersen et al., 2007). Unfortunately it seems that the interest kindled in medical school declined following qualification (Baxter et al., 2001; Maidment et al., 2003).

What influences choice of psychiatry as a career?	
Early medical school experience	(Shah et al., 2011)
The influence of more senior doctors	
Aspects related to the working environment	
Interest in, and concern for, the mentally ill	(Brown et al., 2007)
Being more interested in people than diseases	
A greater interest in social aspects of medicine	
An ability to tolerate ambiguity	
Undergraduate medical experience	

While some studies encouragingly show that teaching of and exposure to psychiatry improve medical students' views about psychiatry (Baxter et al., 2001; McParland et al., 2003; Holm-Petersen et al., 2007), Shah et al. (2011) showed that as junior doctors progress through their careers the influence of their undergraduate training diminishes. Worryingly just 2 months after qualifying interest in a potential career in psychiatry had fallen to 1.9%. Holding a training post had a positive impact and by the end of training interest had improved to where 4.8% of those studied would consider it a career option.

In understanding why interest in psychiatry declines a number of authors looked at students' views of psychiatry (Feifel et al., 1999; Aghukwa, 2010; Rajagopal et al., 2004) and why students who held positive views about the specialty subsequently chose not to pursue it as a career (Lambert et al., 2006).

One study (Wigney and Parker, 2007) found that a perceived lack of scientific underpinning and the attitudes of doctors from other branches of medicine were hugely influential. The impact of the negative views of other medical professionals have been replicated in several studies (Feifel et al., 1999; Shah et al., 2011; Brown et al., 2007; Lambert et al., 2006) along with the belief that there was a lack of science to back up practice and treatment (Malhi et al., 2003; Silvermann et al., 1983; Shah et al., 2011; Lambert et al., 2006) – somewhat ironically perhaps at a time when commentators outside the medical profession continue to attack the perceived reliance on biological models.

In addressing how to deal with this recruitment challenge while some authors have suggested targeting those who are more likely to choose psychiatry as a career (Pidd, 2003; Malhi et al., 2003) it has been argued that this is unlikely to have any significant effect in the light of the relatively small numbers involved and the effect of training post-qualification (Lunn, 2011). More important is likely to be increasing exposure to psychiatry in these first two training years and demonstrating to colleagues the effectiveness of treatment and the evidence base behind practice.

Assessment

The assessment of knowledge has been the primary mode of assessment in medicine due to its relative ease of development, implementation, and high reliability but the importance of assessing skills while still achieving high reliability has led to significant work in assessment over the last 50 years. As educational theory has developed there has been a shift in the view of educationalists as to the purpose of assessment with greater focus on the needs of the learner rather than the teacher or assessing institution. That being said the need of the regulator, and ultimately the patient, has primacy at the end of the day. This becomes the *de facto* 'finishing line' for candidates and gives focus to the aphorism that assessment drives learning.

Assessment is always done with a purpose. That purpose may be to inform the learner/teacher as to how they are progressing (formative assessment) or to come to a decision about competency at a moment in time (summative assessment). The competence may relate to selection, progression, or qualification.

Depending on the purpose of the assessment test selection will vary. High reliability testing will tend to be structured and standardized, for example, using one of the varieties of multiple choice type questions or 'objective' clinical tests (of which more is discussed later) and these often provide little usable feedback to the candidates. Formative testing, because it does not define a change in state for the candidate (and is unlikely to be subject to challenge), can be more varied and should have a primary focus of providing feedback to the candidates. It is commonly argued that assessments are either summative or formative but in reality all assessments will have a mix of both, with the balance of the mix shifting according to the purpose.

It is important for bodies responsible for regulation of the medical profession, such as national regulatory bodies, to be able to provide credible evidence that those certified by them have achieved defined educational outcomes. This has led to the development of national licensing examinations such as the United States Medical Licensing Examination (USMLE) and in the UK developments overseen by the Medical Schools Council Assessment Alliance (MSCAA), which are covered below. The primary focus of such assessment is summative and feedback is limited.

The USLME has three steps. Step 1 is an 8 hour online multiple choice examination that aims to assess understanding and application of important concepts of those sciences basic to the practice of medicine. Special emphasis is placed on the principles and mechanisms underlying health, disease, and modes of therapy. Step 2 has two components – another MCQ and a clinical examination using 12 simulated patients. It aims to assess application of medical knowledge, skills, and understanding of clinical science essential for the candidate to be able to provide patient care under supervision and includes emphasis on health promotion and disease prevention. Step 3 uses formats similar to Step 2 and aims to assess application of medical knowledge essential for the unsupervised practice of medicine, with emphasis on patient management and leads to a license to practice medicine without supervision.

In the UK the MSCAA was set up in 2010 to share assessment items among the 33 UK medical schools as an alternative to the introduction of a national licensing examination. Along with developing this shared question bank the MSCAA works in partnership with the Foundation Schools to deliver the national SJT and British Pharmacological Society to develop and deliver the Prescribing Safety Assessment (PSA). For the first time the PSA was taken by all UK final year medical students in 2014. In most universities this was used as a formative examination but if a student does not pass she/he either has to pass at re-sit, or pass an alternative, locally administered prescribing assessment to be able to prescribe and progress to full registration.

Assessment for specialty qualifications in psychiatry varies significantly between nations with assessment of knowledge being the only common element across all licensing bodies. At specialty level there is significant variation in who provides recognition of attaining specialty status. This ranges from nationally administered bodies, through the profession itself in

specialty bodies such as the Royal College of Psychiatrists in the UK to individual universities.

Many of the bodies that confirm specialist qualifications have sought to define specific competencies in the hope of standardizing requisite behaviors and skills (Accreditation Council for Graduate Medical Education (ACGME), European Board of Psychiatry (2009), Royal College of Psychiatrists, Royal College of Physicians and Surgeons of Canada) that define competent practice. The Royal College of Physicians and Surgeons of Canada in one of the early attempts to do this introduced the CanMEDS Competencies in 1996 (Frank, 2005; Zaretsky, 2009). This defined a series of roles that were thought to be central to doctors providing optimal health care. These not only drive competency based examinations but inform work place based assessments in a number of countries, not just Canada.

Professional

Clinical Skills Assessment

Reliable and valid clinical assessment, assessment of what doctors do, is perhaps the key assessment that medical students and trainees undergo. The traditional 'long-case,' the assessment of a doctor in a setting as close to clinical practice as is possible, has been in decline as it was not without its pedagogic issues. There has therefore been considerable effort in medical education to address this and find suitable alternatives.

Modes of Clinical Assessment

The Long Case

As briefly mentioned in the preceding section, the long case has been the primary mode of clinical skills assessment. In this form of examination the candidate is placed in a room with a patient and required to assess her/him and from the findings develop a diagnosis and management plan. The examiner(s) would only tend to see the candidate after this phase was completed and so assessment is largely a viva voce examination, perhaps including a brief practical element where some clinical signs would be demonstrated in front of the examiner(s).

While the long case appears to have high face validity, as it involves assessment of real patients and requires 'higher order' clinical skills such as the integration of clinical findings and knowledge, a primary problem is that it is unusual for the candidate's interview/examination of the patient to be more than briefly observed. As a consequence key clinical skills are often assessed by inference *post hoc* in the *viva voce* phase. An obvious solution is to observe the whole assessment (Newble, 1991) but this is hugely resource intensive and realistically assessment can only be on one or two cases in total.

The use of real patients is the strength of this form of examination but introduces other difficult-to-control variables. One such variable is the element of 'luck,' which may play to candidates' strengths or weaknesses. This will principally be from the case selection, which will depend on what patients are available to the organizers at the examination center, determined by the nature of the local clinical service. No two 'real' patients with the same disorder will present with the same symptoms and signs. Not limited to psychiatry but perhaps most obvious in this clinical setting, the readiness or otherwise of patients to disclose their history can be independent of a candidate's performance. Of course not only patients are subject to variation – examiners bring a variable skill mix and their own sets of prejudices and preferences. To control for the variability of this form of examination requires multiple cases with multiple examiners. A single long case of an hour has a reliability of only around 0.60 rising to 0.86 after 4 h of testing (Wass and Jolly, 2001); a logistical impossibility for many assessment boards. This can also mean that limited sampling impacts both reliability and validity.

The Modified Long Case

Efforts to address the issues that affect reliability, as described in the last section, led to the development of a modified long case format, the Objective Structured Long Examination Record (OSLER) (Gleeson, 1997). This requires the observation of the candidate's clinical skills and codifies assessment of the presentation of the case, their conclusions, and recommendations by use of a structured oral examination. Typically this still leaves the issues of logistics. A variation of the OSLER the Multiple Objective Structured Long Examination Record (MOSLER) was developed to try and address this later problem. Cases are shorter and focused, which allows for multiple cases and examiners. Nesting of multiple variables makes assessment of reliability difficult but there is some evidence that this is within the range desired by regulators (Wright et al., 2013) with high validity and acceptability to patients, candidates, and examiners alike.

The Objective Structured Clinical Examination

The Objective Structured Clinical Examination (OSCE) was developed out of a desire for a clinical examination that allowed objective assessment of clinical skills (Harden and Gleeson, 1979). A circuit of 'stations' that allow assessment of a variety of clinical scenarios where candidates' skills in dealing with the chosen assessment objectives are tested. With multiple scenarios and examiners this form of assessment can achieve much higher reliability in the same time it would take to carry out two long cases. Additional benefits are that one can define a blueprint of assessment objectives that matches learning outcomes (Lunn, 2005) and control of patient variables with the use of simulated patients (see Section Patient Involvement).

The OSCE wasn't used in psychiatry until relatively recently (Famuyiwa et al., 1991) but has now an evidence base for its use in undergraduate and postgraduate assessment. In the UK the Royal College of Psychiatrists developed an OSCE that was used for the first clinical assessment (Tyrer and Oyebode, 2004). Although this was discontinued following an overhaul of their assessment processes it lives on in all but name in the current final clinical examination, the Clinical Assessment of Skills and Competencies (CASC).

The ability, consequent on the use of simulated patients in the OSCE, to allow structured, replicated, assessment of skills in such a way as would not be possible if real patients were used, is a real advantage of this assessment tool. That said, concerns have been voiced regarding the verisimilitude of the clinical encounter and empathic engagement of candidates. Studies have suggested that this is not a particular issue (Sanson-Fisher and Poole, 1980) and that OSCEs and long cases allow assessment of clinical competence 'no worse and no better' than each other (Wass et al., 2001) and that OSCE skill assessment correlates reasonably with workplace performance (Melding et al., 2002).

The qualitative data from OSCEs has allowed assessment between various demographic groups. As is the norm in most examinations women tend to do better than men. It is interesting to note, however, that in the CASC this is not statistically significant when UK primary medical qualification (PMQ) candidate gender groups are compared. It remains highly significant for the non-UK PMQ groups. A number of factors are probably contributing to this. One is that the UK PMQ candidates' training in medical school closely fits to what is being assessed in the post-graduate arena. The clinical context, which carries its own cultural character, will advantage those with prior knowledge and who are comfortable with it as will language, particularly colloquial language. While congruous with real clinical practice these variables are independent of clinical knowledge and, perhaps, clinical skill. Accepting that the MRCPsych is an assessment of the ability to practice as a specialist in the UK puts this in context, as does that similar patterns of performance have been found in Canadian and Australasian specialty examinations. This emphasizes that the culture of society and psychiatric practice and the idiom of language all play a role in the ability to carry out a specialist clinical role.

The original OSCEs were structured around highly operationalized checklists. This checklist based approach carries problems with it for psychiatry. It has been highlighted that more experienced candidates, with higher order skills, can do less well than less experienced candidates when such checklists are used (Hodges et al., 1999) and that more global 'expert' judgment has higher value in psychiatry.

Workplace-Based Assessments

Miller classified clinical skills according to a pyramidal hierarchy (Miller, 1990). In this structure, 'knowledge' forms the base on which the clinical competence is built. Traditional assessment methodology has placed emphasis on the lower tiers of his pyramid and only with objective driven assessments do candidates begin to be assessed on the ability to show how they do something (performance). Yet there is a need to assess how doctors actually do something (action in Miller's hierarchy). This has led to the use of workplace based assessments (WPBA) (**Figure 2**).

Figure 2 Framework for clinical assessment. From Miller, G.E., 1990. The assessment of clinical skills/competence/performance. Academic Medicine. 6 (Suppl.), S63–S67.

Initial enthusiasm began to be tempered by the realization that when doctors formed working relationships with those they subsequently had to assess there was a 'failure-to-fail.' In the UK this led, in the Foundation years, for the Academy of Medical Royal Colleges to shift the emphasis from these assessments being summative to formative. Candidates are then assessed against their engagement remediating any identified learning needs. While with independent assessment high reliability can be achieved with such assessments (Norcini et al., 2003) the logistics of such methodologies tend not to support such independent assessment.

The driver for regulators in recent years has been to ensure assessment is reliable. This does carry with it a shift in emphasis to methods that can diverge from real clinical practice. Authors such as Hodges have begun to argue that there needs to be a reappraisal of the value of subjectivity. Hodges argues that multiple assessments addressing the single question of whether the individual marking the candidate would be happy for them to treat someone they care about have greater validity and can be reliable when sufficient numbers of such assessments are performed. Key to this is the provision of comprehensive feedback explaining why the assessor made the decision they did. In this form individual assessments have high value as formative assessment and low summative value. Cumulatively the formative value remains and the summative value increases to the point where it has real value and is reliable (Hodges, 2013). Most importantly this methodology has a greater chance of influencing student learning.

Life-Long Learning

Of course learning does not end when formal education ends. If a psychiatrist does not continue to learn then very quickly she/he will fall behind the curve of best medical practice and as a consequence will be a poorer doctor for it. This has long been recognized by the profession and lifelong learning has been supported by professional organizations such as the Royal College of Psychiatrists and the American Psychiatric Association (Bourgeois et al., 2009) through conferences, workshops, and courses and lately by provision of online learning materials.

Regulators have caught on to the importance of this and through licensing and revalidation requirements now assess doctors' engagement with lifelong learning. Tools include peer review, involvement of patients, students, trainees, and nonmedical colleagues through 360° feedback and mandatory participation in learning. Eventually as with everything regulators do, this will become increasingly focused on reliability at the expense of validity and structured examinations will be imposed.

Conclusion

Therefore, Walton's 'creative ferment' has not died down and it is not likely to in the near future. For the moment there are two competing drives in the pedagogy of psychiatry. On one hand regulators seek greater reassurance with a focus on reliable, standardized assessments and curricula that can support high stakes decisions and can be defended in court. On the other, educationalists are arguing for a return to valuing validity of and making the learner the center of the pedagogic process. These need not be mutually exclusive but those who hold the purse strings are unlikely to dispense the largesse that would support, for example, high validity, reliable assessments. Such investment is justified, however, and as Robinson has argued (2006, 2010), our current system reduces education to an industrialized 'fastfood' output model where we need and want individualized, customized product.

Considering that the problem of recruitment in psychiatry seem universal and perennial it would be easy to become disheartened, but there has been a fundamental change in that all the issues raised are being discussed openly and there appears to be a desire from regulators, governments, and from within the profession to find creative solutions to these issues.

Education in South Asia

R Malatesha Joshi, Texas A & M University, College Station, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

According to the South Asian Association for Regional Cooperation, eight membership countries are Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka form South Asia. After a brief background of these countries, the literacy rate is provided based on the Central Intelligence Agency World Fact Book (2009). The literacy rate is low in most of the countries compared to the international average due to poverty and lack of educational facilities. Despite the nations' emphasis on free and compulsory education as well as child labor laws, many children still do not go to school and work in the field because of economic situations. Males generally have a higher rate of literacy rate than females. The educational system in various countries is reviewed and surprisingly similar in terms of the classification of levels into primary, secondary, and high school levels. Most of the nations support teaching two languages or more from early grades.

Introduction

The concept of a group of countries that could be classified as South or Southern Asia may be attributed to Ziaur Rahman, former president of Bangladesh. President Rahman, in 1977, recommended that a group, known as South Asian Association for Regional Cooperation (SAARC) be formed to demonstrate self-reliance in technology, economic, as well as social and cultural development. However, SAARC did not come to fruition till December 1985 and at the present time, is headquartered in Kathmandu, Nepal. The original seven founding members were Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka. The number of countries was increased to eight in 2005 when Afghanistan joined the group. Similar to Group of 8, heads of state usually meet once a year. United Nations Statistical Division (2011), on the other hand, designated the following countries as 'South Asia': Afghanistan, Bangladesh, Bhutan, India, Iran (Islamic Republic of), Maldives, Nepal, Pakistan, and Sri Lanka. It should be noted that the United Nations specifically points out that the countries designated as 'South Asia' is purely for statistical convenience rather than to any political, religious, or linguistic affiliations. South Asia, sometimes is also referred to as 'Indian subcontinent' (McLeod, 2002), however, according to Bose and Jalal (2004), South Asia is preferred rather than Indian subcontinent. It appears that there is no clear classification for the area defined as 'South Asia.' For our purpose, we shall use the term South Asia throughout this article, and would include the eight countries (Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka) included in SAARC.

Even though 'education' can include both formal and informal and can include from preschool or kindergarten to university and postgraduate education, this article addresses only the formal education up to high school level and not discuss university and college education. Further, this article does not discuss about religious schools. Further, I am mostly concentrating on the aspect of literacy and not go into detail about aspects like science or math education. As it becomes clear from the explanation below, there is a lack of disagreement about the definition of literacy as well as the rate of literacy from different reports.

Literacy, according to United Nations Educational, Scientific and Cultural Organization (UNESCO, 2004), "is the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy involves a continuum of learning in enabling individuals to achieve their goals, to develop their knowledge and potential, and to participate fully in their community and wider society" (p. 13). As can be seen, this is a broad definition that includes computation, communication, and participation in community and wider society. The National Assessment of Adult Literacy (White and Dillow, 2005) defines literacy more from the perspective of reading and writing skills and provides two types of definitions: 'task-based (conceptual)' and 'skills-based (operational).' Task-based definition is mainly related to performing literacy tasks and is defined as the "ability to use printed and written information to function in society, to achieve one's goals, and to develop one's knowledge and potential" (White and Dillow, 2005). As the name indicates, skills-based definition refers to the successful use of printed material at the word-level reading skills and higher level literacy skills. For our purpose in this article, we shall define 'literacy' broadly to refer to reading and writing skills.

The definition of literacy as the ability to read and write is also similar to the one suggested by the World Fact Book (2009), published by Central Intelligence Agency (CIA) of the United States, except that the literacy rate is based on anyone above 15 years of age who can read and write. Even though the CIA definition may be acceptable, the method used in assessing the literacy rate may be questionable. CIA might have assessed the literacy rate by asking individuals whether they can read and write; or might have asked to complete a survey. Naturally, people might have answered affirmatively for the question whether they can read and write and perhaps, only those who can read and write might have completed the survey. For instance, according to the World Fact Book, the literacy rate of the US is listed as 99% for the total population and the percentage is the same for both males and females as well. However, according to the report by the National Center for Education Statistics (NCES) (1999), one-third of fourth graders cannot comprehend simple texts and in the case of students from the minority groups almost two-third of the students have difficulty in reading and writing. Additionally,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92143-3

one-fourth of the adults have difficulty in reading a newspaper. It is under this light that the statistics has to be interpreted that I have reported in this article. Due to lack of empirical research in many of the nations in South Asia, I have relied on the information provided by the World Fact Book.

Afghanistan

The official name of Afghanistan is the Islamic Republic of Afghanistan and is a landlocked county bordering Pakistan and Iran, with a population of about 29 million people. The two official languages of Afghanistan are Persian, also known as Dari, and Pashto. Both languages belong to the Indo-European family and Iranian subfamily. The writing system of both Dari and Pashto may be traced back to the Arabic system even though there may be differences from region to region.

According to the World Fact Book (2009), the literacy rate, based on the 2001 census, for the total population is 28.1%, with 43.1% of males and 12.6% of the females being literate. Even though women made up 40% of the doctors and 60% of the teachers at Kabul University in 1988, due to the wars, the number, especially education of females, has been seriously neglected. According to the report from International Institute for Educational Planning (UNESCO, 2011), in 10 years from 2001 to 2010, primary school enrollment increased from 1 million to 7 millions with an increase of 37% among females. Even though some improvements have been made in school buildings, only half of the buildings can be considered as usable. Beginning 2010, the United States started several schools known as Lincoln learning centers in Afghanistan. The purpose of these centers is to offer English language classes, provide library facilities, Internet access, educational and other counseling services. There are approximately 20 such centers and aim to reach at least 4000 Afghan citizens per month per location (U.S. Dept. of State, 2011).

In addition to the problem of wars, poverty, lack of school building, an Afghan student might face another problem in learning to read and write – the diglossic nature of the language. Diglossia, according to Ferguson (1959), is when one form of the language is used for ordinary and informal conversations and the other form of the language is learned largely by formal education and is used for mostly written and formal spoken purposes. Perhaps, the initiatives from UNESCO and the US could improve the education and literacy development for both boys and girls in Afghanistan.

Bangladesh

The official name of Bangladesh is the People's Republic of Bangladesh and is located in South Asia bordered by India and Burma with a population of about 160 million. Original split from British India in 1947, it was called East Pakistan, but became an independent country in 1971. The capital city is Dhaka and the official language is Bengali and English is quite common. Bengali belongs to the Indo-Aryan language family and is the sixth most spoken language in the world. The written language is fairly transparent.

According to the World Fact Book (2009), the literacy rate, based on the 2001 census, for the total population is 47.9%, with 54% of males and 41.4% of the females being literate. Educational levels in Bangladesh can be classified into three segments – primary level ranging from grades 1 to 5; junior secondary level from grades 6 to 8; secondary level from grades 9 to 10; and higher secondary level from grades 11 to 12. There are options to attend government-supported schools as well as private schools, where English instruction may be more popular. The government funds most of the schools and may provide some funding for private schools also. Bangladesh conforms to education for all principles and the primary level, (grades 1–5; 6–10 years of age) is free and compulsory for all students in government schools. Further, the government encourages education for females by providing free education up to grade 10 as well as stipends to continue education. Even though education in Bangladesh is supported by the government and has a good model, because of poverty, there are various problems. The problems include high teacher–pupil ratio in primary schools, perhaps on the average of 45 students per teacher, high teacher absence ratio, high dropout rates, as well as grade repetition (UNESCO, 2007).

Bhutan

Kingdom of Bhutan is the official name and is bordered by the Himalayan mountains and India, with a population of approximately 700 000 (World Fact Book, 2009). Despite poverty, Bhutan is considered the happiest country in Asia and the eighth happiest in the world (Business Week, 2006). The capital of Bhutan is Thimphu and the official language is Dzongkha, even though English is widely used. Dzongkha belongs to Sino-Tibetan language family and the orthography is fairly transparent. The World Fact Book (2009) reports the literacy percentage rate of Bhutan, based on 2003 estimation, as 47, 60, and 34, for the total population, males, and females, respectively. The Government of Bhutan provides free and compulsory education at the primary level, which consists of grades 1–5. Grades 6–8 are called the junior high school and 9–11 make up the high school. Due to the distance, most of the junior high and high schools are boarding schools. English is the medium of instruction in majority of the schools at the junior high and high school levels. Recently, some private schools have been started in big cities like Thimphu, which are mostly boarding schools and the medium of instruction is English. The primary aim of many of the private schools is to prepare students to attend universities. Due to the proximity, many students also go to study in India.

India

The official name of India is The Republic of India and is bordered by Pakistan, China, Burma, Bangladesh, Nepal, and Bhutan. It is the second most populous country with over 1.2 billion people and the most populous democracy in the world. The capital city is New Delhi and the official languages of India are Hindi and English. Hindi is an Indo-European language, written in Devanagiri script and fairly transparent. Additionally, there are 22 official languages in India mainly based on the different states yet, the speakers of these languages

may be in the millions, like, Bengali, spoken in West Bengal, is the sixth most spoken language in the world. Generally, most of the major languages from Northern India can be considered as belonging to the Indo-European family while most of the major South Indian languages can be considered as belonging to the Dravidian family, yet both of them have fairly transparent orthographies. The scripts of the two families are different as well. Additionally, there are thousands of dialects. According to the CIA World Fact Book (2009), the literacy rates of India, based on the 2001 census, are 61%, 73.4%, and 47.8%, respectively for the total population, males, and females. India defines literacy as anyone of 7 years of age and above who can read and write with understanding. Based on this definition, according to the recently completed 2011 census data, the rates were 75.06%, 82.14%, and 65.46% for the total population, males, and females, respectively (The Hindu, 2012). Because of the size of the country and different initiatives, there are differences in the literacy rate among the 28 states, with the state of Kerala reporting a literacy rate of 94% and the state of Bihar reporting 64%. Even though, there may be some minor differences in the classification of different levels, broadly 1–12 grades can be divided into primary level, from grades 1 to 4; middle school level, from grades 5 to 8; and high school level, from grades 9 to 11. However, beginning 2013, the levels will be changed to 12 years of formal education with an additional year at the high school level. Majority of the schools are run by the government and the small number of private schools are very expensive. Because of the infrastructure of the country, many schools, especially in rural areas are overcrowded, lack text books and writing materials like pencils and books. However, the private schools have smaller classrooms and equipped with modern facilities like computers. There are also several international schools primarily for expatriates even though many native Indians attend them. India follows the three-language formula in schools, which means, by the time students enter high school, all of them should have learned three languages – Hindi, English, and a regional or another language.

Maldives

The official name of Maldives is the Republic of Maldives and is also known as the Maldive Islands, with about 1200 islands. It is an island nation in the Indian Ocean and has several distinctions such as one of the smallest countries in the world in terms of area as well as in population, with about 328 000 people (World Fact Book, 2009). It is also one of the world's most geographically dispersed countries. Other distinctions include, planet's lowest country and the country with the lowest natural highest point in the world. The capital city is Malé and the official language is Dhivehi, which is an Indo-Aryan language. Dhivehi, similar to Arabic, is also a diglossic language, where there is a clear difference between the spoken and written formats of the language. The CIA World Fact Book (2009) places Maldives having a high literacy rate. Based on the 2006 census data, the rates were 93.8%, 93%, and 94.7%, respectively, for the total population, males, and females. Maldives follows the universal primary education and is free; even though most of the schools offer primary and secondary education, higher education is continued in other countries, such as India, Sri Lanka, and England. English is widely used in schools even though Dhivehi and Arabic are also included in the school curriculum. Based on the CIA World Fact Book, apparently education is successful in the Maldives with such high literacy rate.

Nepal

The official name of Nepal is the Federal Democratic Republic of Nepal and is a landlocked country bordering India, China, and the Himalayan mountain range. The country has a population of about 27 million people and the capital city is Kathmandu. The official language is Nepali or Nepalese, which belongs to the Indo-European language family. It is written in Devanagari script and the orthography is fairly transparent. According to the CIA World Fact Book (2009), the literacy rates, according to 2001 census data, are 48.6%, 62.7%, and 34.9%, respectively for the total population, males, and females. Beginning with 6 years of age, grades 1–5 are referred to as primary level, grades 6–8 are referred to lower secondary, grades 9–10 referred to as secondary school, and grades 11–12 referred to as higher secondary level. There are both private schools and government-supported schools, with most of the private schools having better facilities. Similar to many countries in the region, Nepal also has problems with overcrowded schools, lack of facilities in terms of books and school buildings, as well as easy access to schools.

Pakistan

The Islamic Republic of Pakistan is the official name of Pakistan and is surrounded by India, Afghanistan, and China. The population of Pakistan is approximately 177 million and the capital city is Islamabad. Pakistan has two official languages: Urdu and English. Urdu language belongs to the Indo-European family and the script is written from right to left and is influenced by Persian and Arabic writing systems. As Urdu language is influenced by Arabic language, it exhibits 'diglossic' characteristics having separate forms of formal literary language and a less formal spoken language. According to the CIA World Fact Book (2009), the literacy rates, according to the 2005 census, were 49.9%, 63.0%, and 36.0%, respectively, for the total population, males, and females. The ministry of education of the Government of Pakistan defined literacy as "anyone age 10 and over who can read a newspaper and write a simple letter, in any language" (Ministry of Education, 2009). According to this criterion, the literacy rates, based on the Pakistan Social and Living Standards Measurement Survey 2008–09 census, were 57%, 69%, and 45%, respectively, for the total population, males, and females. Similar to the educational system in other areas of South Asia, the education system of Pakistan has primary level, from grades 1 to 5; middle school level, from grades 6 to 8; high school level, from grades 9 to 10; and higher secondary school, from grades 11 to 12. Both Urdu and English are taught in schools from the beginning. The Ministry of Education (2009) report provided a bleak report on the institutional facilities in public or governmental schools: about 60% of the schools did not

have electricity; about 37% did not have boundary walls and bathroom facilities; about 35% did not have drinking water facilities. The percentages may be even higher in rural areas and girls' schools (p. 148). Memon (2007) further strongly criticized the status of the educational system by commenting about the shortage of teachers, poor laboratory equipments, overcrowded classrooms, and the poor quality of teachers.

Sri Lanka

The official name of Sri Lanka is Democratic Socialist Republic of Sri Lanka. It is an island nation in Indian Ocean near India, with a population of approximately 20 million inhabitants. The capital of Sri Lanka is Colombo. Formerly known as Ceylon till 1972, Sri Lanka has two official languages – Sinhala and Tamil. Sinhala, also referred to as Sinhalese, Singhalese, and locally as Helabasa, belongs to the Indo-Aryan branch of the Indo-European languages. Similar to Dhivehi and Arabic languages, Sinhala language also exhibits 'diglossia,' where there is a distinction between literary (formal written) language and the spoken language and the orthography is fairly transparent. Tamil language belongs to the Dravidian language family and also exhibits 'diglossia,' and the orthography is transparent. Tamil is one of the most widely spoken languages in the world and, according to Harte and Heifetz (1988), has one of the richest literatures in the world. According to the CIA World Fact Book (2009), the literacy rates, according to the 2001 census, were 90.7%, 92.3%, and 89.1%, respectively, for the total population, males, and females.

Similar to the many educational systems in the region, educational system in Sri Lanka can be classified as primary education, from grades 1 to 5; junior secondary level, also referred to as middle school, ranging from grades 6 to 9; and the senior secondary school from grades 10 to 11. Sri Lanka has the universal education for free till grade 9, till 14 years of age, even though the government encourages students to continue schooling. The medium of instruction is either in Sinhala or Tamil languages. However, there are many international and private schools where English is the medium of instruction (Ministry of education, 2012). Since the end of Civil War in 2009, there has been much improvement in the educational system in Sri Lanka. These improvements include establishing schools in the war-torn places and permitting opening of international schools. The private and international schools have modern facilities but the fees are high and hence can be expensive. The provincial and national schools are less expensive as they are funded by the government but suffer from high teacher–pupil ratio and lack of text books and facilities. There have been some concerns expressed by parents and academicians that the educational system is rigid and competitive, not encouraging creative thinking but encouraging rote memory learning.

Conclusions

South Asia, comprising of eight countries, Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka, is one of the most populous regions and perhaps one of the poorest regions in the world, with high malnutrition and high rate of infant mortality (Ibn live, 2010). These reasons also are reflected in the poor educational opportunities for all school-age children. The educational system from grades 1–12 is very similar among South Asian countries with 3–4 broad levels of classification beginning with the primary level lasting for 4–5 years and completing in 2–3 years of high school or higher secondary school. All the countries have free and compulsory education till at least 10 years of age, yet many countries have not strictly followed the rules due to socioeconomic conditions and child labor practices. In general, males have higher percentage of literacy rate and also complete higher grade compared to females. Even though the literacy rate is obtained from the CIA World Fact Book, the rate has to be verified again as how the data were collected is not very clear and may not be based on empirical research. It is interesting, however, to note that all countries encourage learning of two or more languages from early school years.

Abstract

International declarations, conferences on education as well as international financial institutions have greatly influenced education in Sub-Saharan Africa. This article looks at the current trends of education in the region such as high enrollment rates after the introduction of free basic education, challenges of retaining pupils in the system, poor levels of attainment as well as the prevailing factors in the region affecting the teaching process and profession.

This article also highlights the countries in the region that are faring well on the different issues raised, as well those that are really struggling and later gives some recommendations.

Introduction

Education has a lot of benefits, which the developed as well as developing countries have been enjoying. This includes improved health, increased per capita income, and sustained democracies. Furthermore, education enables people to live with dignity and improve the quality of their lives (IOB, 2011; Yahie, 2000; Spaull, 2011; UNESCO, 2006). Inasmuch as education is a human right, only a few people in Sub-Saharan Africa have the privilege of being educated and so the region cannot really tap benefits such as increased economic growth since the masses are largely steeped in poverty, disease, and other social ills. Although world conferences such as the 1990 Jomtien Conference on Education for All (EFA) and the 2000 World Education Forum in Dakar have helped to highlight the need for concerted efforts in actually making education a human right, 'Education for All' still remains great a challenge in Sub-Saharan Africa. In spite of commitment to international treaties and declarations such as the second and third Millennium Development Goals (MDGs): 'ensuring that all boys and girls *complete* a full course of primary schooling by the year 2015' and '*eliminating gender disparities in primary and secondary schools*', respectively, all education indicators are below world and developing country averages. Most children especially girls are still deprived of the right to education (World Bank, 2008; UNESCO, 2009).

This article will review the performance and challenges of different countries in Sub-Saharan Africa with regard to salient current features of basic education. This includes enrollment rates, attainment levels, and how teachers play a key role in all this.

Background

The 1960s and early 1970s were postindependence era for most countries in Sub-Saharan Africa and they were marked with economic boom. The economic gains were, however, doomed as prices of primary commodities fell, this was further worsened by the oil shocks of the early 1980s as it increased the government deficits and foreign debt (Yahie, 2000). In the 1980s, attempts were made by major financial institutions, that is, the World Bank and International Monetary Fund (IMF) to increase financial stability of developing nations through introduction of Structural Adjustment Programmes (SAP). SAP, however, had negative implications on the public sector, as Kruijer (2010: p. 20) points out that education provision "… was confronted with neo-liberal policies that limited the budget for social expenditures and governments were forced to make choices that restricted public education".

The World Bank (2009) further pointed out that due to the economic crises, governments in developing countries had to reduce the public spending per pupil in primary and secondary

education through stringent austerity measures such as freezing teachers' salaries, increasing class size, and reintroducing school fees. As a result, developing countries experienced a sharp decline in the quality of education provided in institutions of learning subsequent to the 1980s. For example, in Zambia, this led to dilapidated and grossly overcrowded classrooms, that had few or no instructional materials, and demoralized well-trained teachers (Kelly, 1991). Such devastating conditions generally contributed to the impoverishment of the people in the whole Sub-Saharan region. According to Sinyolo (2007), Kelly (1991), as well as Kruijer (2010) the international sanctions imposed on the public sector wage bills forced governments to employ unqualified, volunteer, and contract teachers, which ultimately damaged the quality of education.

With the 1990s came less stringent humane adjustments as both the IMF and the World Bank advocated for good governance and national governments' participation in poverty reduction. After the mid-1990s, national governments like Malawi and Uganda began once again the process of abolishing school fees, often because of promises made during election campaigns (Sinyolo, 2007). In subsequent publications, the World Bank emphasized the need for good quality fee-free primary education, stating it as the basis in governments' poverty reduction strategies (World Bank, 2009).

Clearly, a lot of external as well as internal efforts and energies have been combined in working toward meeting the immediate demands of EFA by 2015 together with those of the MDGs. The results of the policies that focus on meeting EFA and MDG, such as Universal Primary Education are varied but generally influence critical areas of education such as enrollment and retention, as well as teacher supply and literacy.

Enrollment and Retention

Preprimary Schooling

In the Southern and Eastern Africa Consortium for Monitoring Educational Quality (SACMEQ) working paper, Spaull (2011) emphasizes that preschools play an important role in readying the student for primary education by imparting the emotional, intellectual, and social skills necessary to succeed at school. It is further argued that children who attend preschool are more likely to succeed at primary school and less likely to repeat and drop out. In spite of this positive outlook, preprimary education is still viewed as a luxury for nearly all children. Anyhow, access to preprimary education has steadily increased over the years in Sub-Saharan Africa. UNESCO (2009) reports indicate that in 2006, nearly 9 million children were enrolled in preprimary education, up from some 5 million in 1999. In spite of this, the average gross enrollment ratio remained low at 14% in 2006 with huge regional disparities. Spaull (2011) also further indicates that some countries, such as Equatorial Guinea, Ghana, Liberia, and South Africa, have recorded significant enrollment improvements while a few nations like Seychelles and Mauritius have records of over 100% improvement.

Generally, preschool education is mostly provided by private institutions and is concentrated in urban and wealthy areas as it tends to be very expensive. However, in countries like "South Africa and Namibia the government plays an active role in the provision and monitoring of preschool education" (Spaull, 2011: p. 54). (Refer to Figure A.1 in the Appendix for the enrollment trend between 1999 and 2006.)

Primary Education

In Sub-Saharan Africa, primary education usually stretches over a period of 6–7 years, starting from grade 1 to 6, in places like Nigeria, and all the way to grade 7 in Zambia Mozambique or Zimbabwe.

For the majority of children, this is the first time they set foot in a classroom and enrollment age across the region varies between 6 and 7 years. For example, in Namibia, Benin, and Cameroon children start school at age 6 while in most other countries the formal enrollment age is 7 (World Bank, 2008). It is, however, worth noting that issues of early and late school entry are quite widespread with some countries having extreme cases of underage or overage children. For instance, household surveys in Tanzania, Ethiopia, and Ghana indicated that more than 60% of the children in primary school were above the required age for their grade while for countries like Niger, Cameroon, and Uganda underage pupils made up a large share of first graders (UNESCO, 2009). A recent study by Fink et al. (2012) conducted in Zambia on early childhood development also cited early enrollment in school as common practice, with about 25% of children starting school at age 6 or earlier. Countries in the Sub-Saharan region have recorded a sharp increase in the number of children entering primary school since the Dakar conference. The average primary net enrollment between 1999 and 2006 increased from 56 to 70% with some countries such as Tanzania, Zambia, Madagascar, and Benin registering very impressive progress moving from enrollment ratios of 50–70% in 1999 to levels in excess of 80% in 2006 (UNESCO, 2008b).

Tremendous improvement has also been noticed in some countries like Rwanda where between 1998 and 2009 "enrolment in primary school almost doubled with an annual growth rate of 5.4%" (World Bank, 2011: p. 59). Ethiopia is another country that managed to double its enrollment ratio from 34% in 1999 to 71% in 2007 (UNESCO, 2009). Successful strategies have included ambitious school construction programs in rural areas, abolition of school tuition fees and targeting disadvantaged groups like orphans and vulnerable children as has been noticed in several countries. For instance, in Zambia, meeting the increased demand for primary education has also meant constructing more schools, that is from having approximately 5300 basic schools in 2000 to about 8400 in 2010 (with the largest increase in the number of community schools) (World Bank, 2011; IOB, 2011).

On the other hand, there are some West African countries were the enrollment results have been less positive, especially for girls. For example, in spite of some progress made since 1999, Nigeria only showed a net enrollment rate of 63% with gender parity index of 0.83 in 2005. According to UNESCO (2008b), this implies that 48% of girls in the primary school age were out of school.

Nonetheless, enrollment disparities within countries are also very pronounced and sometimes even greater than between countries. Generally, children living in the urban areas

are enrolled at higher rates than their rural counterparts and the gaps tend to increase as they move up the educational ladder. "Disparities within the countries based on wealth, gender, race, language, ethnic group or disability hinder progress towards Universal Primary Education" (Kruijer, 2010: p. 19). In Burkina Faso, Chad, Ethiopia, Mali, and the Niger, Kruijer (2010) further indicates that children from the richest 20% are from three to about four times more likely to attend school than children from the poorest quintile.

So inasmuch as there is a general increment in the enrollment rates of the Sub-Saharan region, it is worth noting that there is still a large number of children below the age of 7 who are still not enrolled in school because of perceived dangers on the way and lack of nearby schools (AAF, 2011; IOB, 2011; UNESCO, 2009). IOB (2011) also observes that in 2006 almost one-third of the school age population in Sub-Saharan Africa, about 35 million children were not enrolled in schools.

Compared to other regions in the world, countries in Sub-Saharan Africa have low enrollment rates and strong gender disparities and inequalities. Significant gender disparities in primary enrollment rates are still reported in many countries. For instance, as is indicated in **Figure 1** below, the Central African Republic, Chad, Cote d'Ivoire, Mali, and Niger have fewer than 80 girls enrolled in primary school for every 100 boys in 2006 (UNESCO, 2009).

Primary Completion Rates

Although there have been marked improvements in access to education for most countries in the Sub-Saharan Africa, there are still large differences in dropout and retention rates. According to Lloyd and Hewitt (2009) Sub-Saharan Africa has the lowest primary completion rates compared to other regions of the world. In instances where there is high dropout and repetition rate many children have a low survival rate to the end of primary school.

"Excessive grade repetition is a common problem in Sub-Saharan Africa" (Spaull, 2011: p. 53). Students who do not achieve the required grade are held back and repeat that same grade in the hope that they will acquire the skills the second time around. UNESCO (2009) indicated that in 2006, the median percentage of repeaters in the region was just above 13%.

Factors such as disease, hunger, child labor, and distant schools make children to be absent from school and eventually drop out. For example, AAF (2011) reveals that in Kenya, 4 out of 10 children miss school on a daily basis mainly due to family support demands and distant schools.

SACMEQ studies done in some countries in Southern Africa have shown variations in reaching grade 6 (as indicated in the Figure A.2 in the Appendix), where Mozambique has a survival rate of 60% while South Africa, Namibia, and Botswana all have high rates of about 90%. In this case, countries like Mozambique have high dropout rates affecting the number of children reaching grade 6 and eventually secondary school (Spaull, 2011).

It is, however, interesting to note that over the past 30 years, the trends in the percentage of boys and girls completing primary school in the Sub-Saharan region have shown improvements (Lloyd and Hewitt, 2009), as can be seen in **Figure 2** below.

Figure 2 clearly shows that in early 2000, approximately 60% of boys aged 10–14 had completed primary school, and over the past 30 years, there has been a slow rise in the completion rate for boys. Over the same period, girls' completion rates have risen steadily almost doubling from 30 to 56% indicating that the gender gap in the region has narrowed steadily and consistently.

Current primary completion rates in the region vary from as low as 8% for girls and 19% for boys in Niger to as high as 90% for girls and 86% for boys in South Africa (Lloyd and Hewitt, 2009).

Secondary

Depending on the country, young people are generally expected to enroll into secondary school from the age of 12 or 14 and are expected to be in the system for 6 or 5 years, respectively. While participation in primary education is expanding, access to secondary education remains limited for most young people in Sub-Saharan Africa. UNESCO (2009) monthly reports suggest that overall enrollment in the region is rising with over 12 million more students in 2006, up from 20.6 million in 1999. Despite this significant trend, 78 million of the region's secondary school age children were not enrolled in secondary school in 2006.

There are a number of factors causing low participation in secondary schools in this region, such as low primary enrollment, low transition from primary to secondary, or high dropout rate. In addition, a large proportion of the schooling capacity is held by students who are repeating grades (World Bank, 2008).

There exists a close relation between secondary and primary enrollments. On average, countries with very low secondary enrollment also have a relatively low primary enrollment and in addition also, a significant gender imbalance. The World Bank (2008) working paper further shows that for countries like South Africa and Namibia with high primary completion rates, secondary enrollments are equally high whereas transition rate from primary to secondary in Tanzania is 21%, Uganda 29%, and Kenya at 53%. (Refer to Table A.1 in the Appendix for a classification). The under representation of girls is a common characteristic of countries with low enrollments rates like Eritrea, Mali, Senegal, and Tanzania. (Refer to Figure A.3 in the Appendix for details).

Transition from lower secondary to higher secondary is a critical dropout point for most countries in sub-Saharan Africa education systems. In 2006, the regional average gross enrollment rate was higher in lower secondary (38%) than upper secondary (24%) with differences in participation rate between the two levels (UNESCO, 2009). Like primary education, within-country inequalities in secondary education are even more marked than those among countries. Secondary school attendance and survival rates to the last grade are marked by disparities related to household wealth and language. UNESCO (2009) also shows that attendance rates of richer households are much more than those of poorer households for instance in Burkina Faso, Guinea, Mali, and Niger.

Figure 1 Changes in gender disparities in primary and secondary enrollment ratios, 2006. GPI, Gross enrollment ratio; GER, Gender parity index. Source: UNESCO, 2009. Regional Overview of Sub-Saharan Africa – EFA Global Monitoring Report, Overcoming Inequality: Why Governance Matters. UNESCO, Paris, p. 8.

Figure 2 Trends in completion of primary school, 33 African countries (population weighted). Source: DHS, MICS-2 data in Lloyd, C.B., Hewitt, P.C., 2009. Poverty Gender and Youth, Educational Inequalities in the Midst of Poverty: Diversity across Africa in Educational Outcomes, Working Paper. Population Council, New York, p. 17.

Inasmuch as enrollment rates and issues of attendance and grade progression are good indicators of achieving universal primary education, they are not entirely adequate because it is not easy to know how well students are performing in the classroom.

Learning Achievement/Educational Quality

High enrollments brought on by the abolishment of school tuition fees in Sub-Saharan Africa have compromised the quality of basic education. One area that has been very crucial is with regard to 'what children learn' and their ability to use the acquired skills. According to the World Bank (2008), the low enrollment in secondary education has been related to broader problems in school attainment and quality of schooling. Student competence levels in numeracy and literacy as well as national examinations have been good indicators of quality with regard to school attainment.

While literacy improves with schooling, the correlation between the two is far from perfect in most countries in Sub-Saharan Africa. In Tanzania, for instance, 1 out of 5 pupils who finish primary education cannot read at a second grade level in Kiswahili and only 5 out of 10 children can read in English upon completion of primary school, which is a debilitating factor as secondary school is taught in English only. In Kenya, 7 out of 10 children in third grade cannot do second grade mathematics and reading work (AAF, 2011).

UNESCO (2006) further highlights the link between poverty and illiteracy in countries with particularly low levels of literacy such as Cote d'Ivoire, Guinea Bissau, Rwanda, Senegal, Togo, and Sierra Leone where the literacy gap between the poorest and wealthiest households is more than 40%.

Furthermore, in some countries like Ethiopia with low overall literacy rates, UNESCO (2006) points out that they are also faced with large urban/rural disparities where urban literacy rates are 74% while rural literacy rates are 23%.

Results from regional assessments have highlighted poor learning outcomes in Sub-Saharan Africa, for example, in 1999 Uganda carried out assessments to determine overall achievement levels in grades 3 and 6 in English literacy and numeracy. Results indicated that in spite of the general increase in achievement levels over time, fewer than half of the children reached defined competence levels in English literacy (UNESCO, 2008a).

Generally, it has been observed that large numbers of children who reach the last grade in primary school have weak literacy and numeracy skills. Results from the SACMEQ study of 2000–02 conducted in 13 Southern Africa countries indicate that hardly any grade 6 students in Lesotho, Malawi, and Zambia reached one of the four highest levels of the numeracy scale while more than a third did so in Kenya, Mauritius, and Seychelles (UNESCO, 2006).

Other SACMEQ assessments conducted in 2000 and 2007 on grade 6 children in various countries indicate that Namibia, Swaziland, Lesotho, and Tanzania registered substantial improvements for both reading and mathematics (SACMEQ, 2010). On the other hand, Mozambique registered substantial deterioration in achievement in both reading and mathematics, as indicated in **Table 1** below.

Table 1 highlights the performance of pupils in reading and mathematics for the years 2000 and 2007, with the arrows indicating either an increase or decrease in performance.

UNESCO (2009) has also observed that girls and boys achieve very different outcomes in school not just in overall performance but also by subject. Recent studies have shown that girls continue to outperform boys in reading literacy and language arts. This is evident in a diverse group of countries including those with great gender disparities in school participation such as Burkina Faso. Although boys have generally outperformed girls in mathematics in all grades of primary and secondary education, there is a general observation that this trend is slowly changing as the girls are increasingly performing at levels equal to or better than boys, for instance in

Table 1 Levels and trends in pupil achievement for SACMEQ countries

Francophone Africa. SACMEQ results of sixth graders have also shown significant male advantages in mathematics for Zambia, Kenya, Mozambique, Zanzibar, and Tanzania but not for Seychelles (UNESCO, 2009).

The deep learning deficits in the region are also confirmed by national examination results. For example, in Zambia with the government's objective that every child completes 9 years of basic education, grade 9 examinations have become more important over time (IOB, 2011). This is reflected in the growth in the number of candidates as is indicated in **Figure 3** below.

Since 2003, the grade 9 examination results have indicated a slight improvement with girls, although on the overall boys achieved significantly better in mathematics. However, in 2009

Figure 3 Grade 9 examination results, 2003–10. Source: Examinations Council of Zambia, 2010. Learning Achievement at the Middle Basic Level, Zambia's National Assessment Survey Report in IOB, 2011. Unfinished Business: Making a Difference in Basic Education. An Evaluation into the Impact of Education Policies in Zambia and the Role of Budget Support. Ministry of Foreign Affairs of the Netherlands, The Hague, p. 98.

girls showed larger improvements than boys both in English and mathematics (IOB, 2011). (See Table A.2 in Appendix for low performance since maximum score is 100 as well as Table A.3 for the grade 7 examinations, which have a total score of 60 points.)

According to Ahonen and Aro (2011), there are a number of factors that may explain the poor attainment levels not just in Zambia but the entire Sub-Saharan region. These include teacher shortages, overcrowded classrooms, poor teaching, primary language interference, lack of printed material in local languages, illiterate parents, and lack of parental support in the learning process.

Teachers and Factors Affecting the Teaching Process

Teachers are the main providers of quality education. In this regard, the way they are recruited, trained, and deployed across the schools is vital for improving learning outcomes. As already alluded to, the introduction of free basic education in Sub-Saharan Africa automatically resulted in more children in the classrooms thereby increasing the pupil teacher ratio. This situation is compounded by the sharp teacher shortages especially in the rural areas. In Tanzania and Kenya, the AAF (2011) reported the pupil teacher ratio to be 72:1 and 47:1, respectively.

UNESCO studies indicate that in 2006 the average pupil teacher ratio across the region was 45:1, up from 41:1 in 1999. However, in countries like Chad, Mozambique, and Rwanda, UNESCO (2009) stresses that the national primary pupil teacher ratio exceeded 60:1.

Larger disparities of pupil teacher ratios exist within countries and they are influenced by location, wealth, and type of school, for instance in the Bayelsa state of Nigeria the pupil teacher ratio is five times higher than Lagos, while Zambian rural schools have a pupil teacher ratio higher than 80 (UNESCO, 2009; IOB, 2011).

Trained teachers are in short supply in many countries in the region and the teacher shortage is often an indication of inadequate investment in education. At primary level, the teacher education is often fragmented, incomplete and in some cases nonexistent. Although governments have realized the need to recruit additional teachers to meet the increasing enrollment in primary education it is difficult to train new teachers when resources are so scarce. For many countries in the region investment in education is inadequate because the governments heavily depend on external funding to support basic education policy and practice. Financial institutions such as the World Bank and IMF are some of the major founders of education programs in developing countries. Kruijer (2010) indicates that in countries like Chad, Togo, and Madagascar fewer than 40% of teachers are trained. To speedily reduce the pupil teacher ratio governments especially in West Africa have decided to recruit contract teachers to work outside the civil service structure. In addition to this, the author highlights that the cost of contract teachers is much lower than civil servant teachers and the length of their education is much shorter.

Due to financial constraints as well as agreements reached with international financial institutions like World Bank, some countries in the region could not deploy teachers coming out of colleges and universities for a long time. For instance, Sinyolo (2007) explains that Kenya and Zambia had 40 000 and 15 000 unemployed qualified teachers respectively, and yet because of the high pupil teacher ratio resorted to using volunteer, unqualified as well as contract teachers. In 2006, Zambia had over 7000 unqualified teachers working in schools while other countries in the region like Gambia had 1600, Lesotho had over 6600 with Tanzania having over 10 000 unqualified teachers (Sinyolo, 2007).

Nonetheless, the use of unqualified teachers brings severe deficiencies which outweigh the financial advantages. Those with limited professional education are likely to provide lower quality education and the fact that they are deployed in the rural understaffed schools means the rural children's attainment levels are adversely affected, further exasperating the rural urban inequalities. For example, in Ghana, untrained teachers are concentrated in the north, which has the lowest economic development and the most out of school children (Kruijer, 2010; UNESCO, 2009).

A number of countries, including those were the IMF had put caps on the public sector wage bill in the region, are, however, making positive progress toward having and recruiting well-trained teachers in the primary schools. Huge progress has been made for instance in Namibia where more than 90% of the teachers had the required training in 2005, up from 29% in 1999. The sharp increase resulted from the policy to upgrade the teacher qualification and replace untrained teachers with trained ones (Sinyolo, 2007; UNESCO, 2008a). A number of countries in Sub-Saharan Africa have been involved in the upgrading program of unqualified teachers, for example, Malawi, Tanzania, and Nigeria. Anyhow, as Kruijer (2010) has pointed out it is not clear if the participation in an upgrading program leads to improved classroom practices. Important to note is the fact that the average academic level of unqualified teachers is low.

Kruijer (2010) further highlights a research report on in-service education in Namibia which revealed that more than three-quarters of the sample of teachers did not demonstrate the desired teaching approaches. Possible reasons for this situation could be the poor teaching conditions that teachers are exposed to such as lack of accommodation, physically inadequate classrooms, a lack of furniture and teaching material as well as high pupil teacher ratio which make it impossible to use the newly learnt teaching skills. Furthermore, when teachers are faced with scarcity of resources and numerous limitations they tend to fall back on their previous traditional schooling practices, such as lecturing (Kruijer, 2010; Kelly, 1991; UNESCO, 2008a).

The World Bank (2008) suggests that other factors that affect the quality of teaching include low salaries which leads to low teacher morale and also results in teachers taking extra teaching loads or other paid work to secure a decent economic outcome. **Table 2** above shows teachers' salaries in 6 countries.

Table 2 Teacher's gross salaries per month in US Dollars (2005–06)

Level	*The Gambia*	*Kenya*	*Lesotho*	*Uganda*	*Tanzania*	*Zambia*
Primary	60	152	177	115	20	200
Lower secondary	75	272	265	144	95	250
Upper secondary	90	305	638	260	125	325

Source: Sinyolo, D., 2007. Education International. Teacher Supply, Recruitment and Retention in Six Anglophone Sub-Saharan African Countries in The Gambia, Kenya, Lesotho, Tanzania, Uganda and Zambia. Education International, Brussels, p. 56.

Due to low salaries and poor conditions of service in most of Sub-Saharan Africa, the status of the teaching profession is declining. This ultimately leads to severe retention problems coupled with high rates of absenteeism. UNESCO (2009) points out that teacher absenteeism rates in primary schools averaged 27% in Uganda. The author further highlights that in other countries such as Ghana, South Africa and Tanzania teacher absenteeism was more pronounced in public schools, schools with poorer infrastructure, in rural areas, in poorer states and in schools serving children from lower socioeconomic backgrounds.

Teacher absenteeism is also associated with low student performance because of the inadequate covering of the curriculum and shorter time on task. SACMEQ studies found that grade 6 South African mathematics and reading teachers were absent for twice as many days as Botswana and Namibian teachers while three times as many days as the average Mozambican mathematics teacher (Spaull, 2011).

Illness and financial problems linked to irregular pay are some of the reasons for high absent rates of teachers in Sub-Saharan Africa. Although teacher mortality rates due to HIV/AIDS are decreasing and reasonably stable, the epidemic is damaging lives and educational systems. For example, in Kenya, about 14 500 are estimated to be HIV positive and 4–6 teachers die each day due to AIDS and opportunistic infections (UNESCO, 2009).

Conclusion

It has been observed that the abolishment of primary school tuition fees in the mid-1990s has had a very positive effect with regard to allowing more children access basic education. Once the policy of free basic education was introduced in the Sub-Saharan region there was a 'new' demand for education from the poor masses that were initially disadvantaged with the introduction cost sharing measures by international financial institutions in the 1980s. This led to increased enrollment rates at primary school across the region (UNESCO, 2009; World Bank, 2009).

Ironically, most governments in the region were not ready for the new demand and so experienced a lot of serious challenges in trying to adequately cater for the increased number of pupils (SACMEQ, 2010). The challenges included lack of classrooms and appropriate furniture, lack of resources in the form of student books and teachers' manuals and lack of trained teachers which ultimately led to questioning the quality of the education offered (IOB, 2011; Kruijer, 2010). What further compounded the challenge was the lack of morale teachers experienced due to low salaries, lack of incentives for progression in the profession and the general poor working conditions they were subjected to. This led to high rates of attrition and absenteeism making the shortage of teachers more pronounced. To fill the gap governments resorted to cheap labor in the form of volunteers and contract teachers who are easy to fire and hire or even send to remote parts of countries which had marked problems of teacher shortages. Seeing most contract teachers were untrained they lacked preservice training and governments in the region quickly provided in-service training to fill their knowledge gap (Sinyolo, 2007). However, the intermittent training has not been very effective as it has been observed that the pupils have been negatively affected in that even after completing primary education they are not ready for tasks in secondary school. This is mainly because of the low levels of literacy and numeracy as well as the low passing rate in examinations.

Recommendations

To completely achieve universal primary education, it is cardinal for the governments in the Sub-Saharan region to set up good collective bargain structures and ultimately allocate more funding to construction of new classrooms that are inclusive even to disabled children. This will also help to improve the teacher pupil contact hours and will eventually reduce the pupil teacher ratio. Furthermore, infrastructure should be advanced with resources such as solar power, electricity, and laboratories. Teacher training also needs beefing up to ensure the presence of qualified teaching personnel who can teach not only the academic but also vocational subjects in order to prepare dropouts with some life skills. Alongside this, the general working conditions of teachers including salaries, housing, and other incentives needed to attract teachers to rural areas should be improved. As regards, the in-service component of the upgrading program, it is important that it be closely monitored and consistently evaluated to allow for adequate mentoring of the students. Additionally, the remedial programs for repeaters both in primary and secondary schools equally need consistent evaluation to make the repeating process more effective.

Abstract

This article analyzes the educational systems in the Middle East and North Africa and highlights the similarities and specificities of countries in the region. The first part describes the structures of the educational systems. The second part identifies the characteristics of the educational systems in four distinct groups of countries in the region with common challenges. The third part analyzes the development of access to different levels of education in the region and discusses the development of mass schooling and higher education. The fourth part deals with the impact of education on societies in the region, analyzing the high rate of youth unemployment and the persistence of illiteracy. The place of religion and cultural diversity in the educational systems of countries in the region are addressed.

Introduction

The region of the Middle East and North Africa (MENA (The MENA region does include Iran. The educational problems of this country are in some ways similar to those of the region. However, this article focuses on the educational situation in Arab countries.)) is characterized by its sociopolitical diversity. The region consists of 22 countries with diverse political regimes (republic, monarchy). The level of educational development varies between those countries with low school enrollment and those which manage to get all of their children into school. Despite disparities in income and literacy level, the region enjoys a fair degree of homogeneity in other respects and is well integrated historically and culturally. A common language (Arabic) and religion (Islam) connect the vast majority of the region's population (Salehi-Isfahani, 2010).

Arab countries concentrate a heavier expenditure on education, as a share of gross domestic product, than the world's average. They have made great strides in eradicating mass illiteracy; in boosting primary, secondary, and university enrollment; and in reducing gender gaps in education. Yet, two recent reports published by the World Bank and the Rand Corporation point out that Arab schools continue to propose programs that are irrelevant to the socioeconomic needs of the population and that do not effectively prepare students for the global economy of twenty-first century (World Bank, 2008; Gonzalez et al., 2008). The teaching approach is mainly based on rote learning and little links exist between school curricula and work settings. The region is very youthful, with 60% of the population aged under 30 years and one-third under 15 years. This demographic fact is both an asset and a challenge. Education, it must be kept in mind, is vital to shaping societies and governments in the near future. Thus, investing in educational reform, today, would encourage democratic citizenship and would help the current quest for an Arab democracy.

The Structures

Contemporary educational structures in MENA countries are linked to colonization. Indeed, prior to European colonization of the nineteenth and twentieth centuries, education in the region was mainly linked to religious Koranic schools, with the exception of the Mediterranean cities where large Jewish minorities and European inhabitants were living. In cities like Tunis, Cairo, Alexandria, Beirut, and Damascus, some modern, Western-style schools emerged before European colonization, offering classes including sciences and foreign languages.

The independence of the Arab countries in the middle of the twentieth century has seen the emergence of educational structures inherited from the former European colonial powers (United Kingdom, France). North African countries (Algeria, Morocco, Tunisia, and Mauritania) and the Levant (Lebanon, Syria) have copied the structures of the French educational system with the use of Arabic as a language of instruction, at different degrees of intensity. Postcolonial bilingualism (French–Arabic) in North Africa has given rise to much debate and controversy until now. The rest of the Arab countries have adopted the structures of the British system with Arabic as the main language of instruction.

Current educational structures of the MENA countries are characterized by the coexistence of public and private institutions. The private sector has, in many contexts, the monopoly of schooling the elites, and reaps the benefits of the associated social prestige.

Another feature of educational structures is the deep centralization of educational structures. Textbooks, teachers, and school legislation are set at the national level. Educational reforms require good governance. Unfortunately, this notion is lacking in the region at the level of the central government, regional administration, and school. Ministries of education assume a highly centralized role and are dominated by top-down authoritarian management systems. Furthermore, most ministries lack long-term vision, appropriate strategic planning, and competent human resources.

Because of wide disparities in income, MENA forms a heterogeneous group of countries from the standpoint of per capita income and educational development. Therefore, it is important that the discussion of their education systems, of which income is one of the most important determinants, be conducted with three groups of countries in mind: (1) High income, oil-rich countries of the GCC (The Gulf Cooperation Council: Oman, United Arab Emirates, Bahrain, Qatar, Kuwait,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92149-4

and Saudi Arabia), and Libya. For these countries, infrastructure and school coverage are similar to those of developed countries. Enrollment rates are high at all levels of schooling. In these countries, higher education is marked by the strong presence of foreign, for-profit universities. A lack of qualified local teachers and managers is observed. (2) Middle income, mainstream MENA countries (Morocco, Algeria, Tunisia, Egypt, Syria, Lebanon, Palestine, Jordan, and Iraq). The educational systems of these countries have a decent infrastructure and enrollment. Residual problems exist in some areas (rural and remote regions). Enrollment rates are high at primary and secondary levels and increasing at the tertiary level. (3) Low-income, periphery MENA countries (Sudan, Mauritania, Yemen, Somalia, and Comoros). These countries need to address the problem of educational infrastructure. Challenges exist at different levels of the educational system such as illiteracy rates, children not in school, and the gender gap.

Quantitative Expansion of Education

Arab countries have gradually improved their school enrollment in the last three decades. According to the United Nations Educational, Scientific and Cultural Organization (UNESCO) statistics, access to primary school has become the norm for most children in the region. Thus, on average, 87% of boys and 82% of girls at each relevant age are currently enrolled in primary education in Arab countries. This has led to significant progress toward universal access to school.

Another element to measure the development of education is to examine school life expectancy. According to the Institute for Statistics (2012), school life expectancy is 14.5 years in Tunisia, 13.7 years in Saudi Arabia, and only 5.1 years in Djibouti. According to UNESCO (2007), the average years of schooling in 2005 exceeded 12 years in half of the Arab countries, and exceeded 10 years in the majority of countries.

This improvement in school enrollment in the region is related to two main factors. The first is linked to the building of the postcolonial states. National elites in positions of power saw education as the top priority, believing that a well-instructed nation can access economic development and reach technological independence. The second factor is linked to oil revenues that have enabled many states in the region to invest in the construction of schools and teacher recruitment.

By national law, most countries in the MENA region offer an average of 9 years of compulsory education, while it is 12 years in the Organisation for Economic Co-Operation and Development (OECD) countries like the United States and United Kingdom (Figure 1).

Despite progress in schooling, 6 million primary school children remain out of school, the majority of whom are girls. Between 1999 and 2005, Yemen, one of the world's poorest countries, witnessed a large increase in enrollment. However, in 2008, it recorded over 1 million out-of-school children, the highest number in the region (UNESCO, 2011). This increase in children out of school has slowed over the past few years. However, that number could increase again as a consequence of the resent political revolts in the country.

The Problem of Educational Quality in the Region

While government expenditure on education in some MENA countries, such as Tunisia (6.9%), Jordan (4.9%), Saudi Arabia (5.6%), and Morocco (5.6%), is higher than in the OECD countries (5.4%) and North America (5.1%) (Al Masah, 2011), all MENA countries have weak educational outcomes:

> Qualitative criteria that deal with such issues as the quality of teachers, curricula, teaching methodologies, facilities, evaluation tools, guidance and counseling services, special services for individuals of special needs, and the nature of out-of-class activities. They also include the extent to which life-long educational services and facilities are available, especially within non-formal education. The progress achieved in the Arab countries according to the qualitative criteria has been modest.
>
> Masri, 2009: p. 134

If the problems of educational quality in the region are not new and are partly related to the legacy of weak colonial

Figure 1 Duration of compulsory education.

schooling (Akkari, 2010) and poverty (Rebouha and Pochet, 2011), what is worrying is the persistence of this situation in comparative perspective (Heyneman, 1997). All of the countries in the region are facing a serious problem, that of the quality of education provided in schools. One of the most convincing indicators to realize the existence of this common challenge is to analyze literacy rate in the region. Most Asian and Latin American countries do better.

Illiteracy rates are particularly high in densely populated countries such as Egypt, Morocco, and Yemen. The illiteracy rate for women exceeds 50% in Mauritania, Morocco, and Yemen. While the literacy rate has been rising in the region, it has not risen fast enough to meet the population growth. The number of adult illiterates is still rising, reaching 60 million in 2008, 18 million of whom live in Egypt. Women have been disproportionately affected in most countries, with women representing over 70% of illiterates in Yemen, Libya, Jordan, and the occupied Palestinian territories. Bahrain, Jordan, Kuwait, Lebanon, Qatar, the United Arab Emirates, and the Occupied Palestinian Territories all had literacy rates above 90% (UNESCO, 2011; **Table 1**).

Another way to approach the quality of education in Arab countries is to situate their ranking in international comparative surveys. When looking at this indicator, even rich Arab gulf countries need to improve the quality of educational institutions at the primary, secondary, and tertiary levels. A common problem that arises across the region is that the educational institutions do not teach young people the skills necessary to succeed in the private sector (Davis and Hayashi, 2007).

The Progress in International Reading Literacy Study, an international comparative study of the reading literacy of young students, ranked all Arab countries, including the rich Gulf States, among the worst performers. In Morocco, for example, a majority of students had not acquired basic reading skills after 4 years of primary education (UNESCO, 2011).

Table 1 Adult (15+ years) literacy rate

Country	*Literacy rate (%)*
Algeria (2006)	72.6
Bahrain (2009)	91.4
Egypt (2006)	66.4
Iraq (2009)	78.7
Jordan (2007)	92.2
Kuwait (2008)	93.9
Lebanon (2007)	89.6
Libya (2009)	88.9
Mauritania (2009)	57.5
Morocco (2009)	56.1
Palestine (2009)	94.6
Oman (2008)	86.6
Qatar (2009)	94.7
Saudi Arabia (2009)	86.1
Sudan (2009)	70.2
Syria (2009)	84.2
Tunisia (2008)	77.6
United Arab Emirates (2005)	90
Yemen (2009)	62.4

Source: UIS. 2012. Data Centre: UNESCO Institute for Statistics.

A survey called Trends in International Mathematics and Science Study, which comes out every 4 years, revealed in its latest report, in 2007, that out of 48 countries tested, all 12 participating Arab countries fell below the average. More disturbingly, less than 1% of students aged 12–13 years in 10 Arab countries reached an advanced benchmark in science, compared with 32% in Singapore and 10% in the United States. Only one Arab country, Jordan, scored above the international average, with 5% of its 13-year-olds reaching the advanced category. Education in the Arab world lags behind that in other regions. The region had not witnessed the positive changes seen in Asia and Latin America, particularly in literacy rates (World Bank, 2008).

Internationally comparable reading test scores at grade four show that, in Kuwait, Qatar, and Morocco, over 90% of the students scored lower than the minimum benchmark, which indicates that the students have not acquired basic reading comprehension after at least 4 years of schooling. The results do not improve over time either. Math and science scores for grade eight show that the majority of students in Algeria, Egypt, Saudi Arabia, Syria, and Qatar are below the minimum threshold (Adams and Winthrop, 2012).

The low quality of education in the region is directly related to teacher quality. However, the number of trained teachers and their professional development are still neglected by policy makers:

> The current shortage of qualified teachers, especially at the primary and secondary levels, is due to several factors. These include low teacher wages and inefficient school management, which do not entice the best and the brightest to enter into the academic profession.
>
> Maroun et al., 2008: p. 14

UNESCO pointed out that the future shortage of quality teachers threatens the goal of education for all, and requires that the Arab States create 450 000 new teaching posts, mainly in Egypt, Iraq, Morocco, and Saudi Arabia (UN News Center, 2006). Furthermore, the causal link between the recruitment of female teachers and girls' enrollment and retention is direct and very significant. There is also evidence that the lack of a school close to the home raises concerns for the safety and security of girls (Alim, A., et al., 2007).

A pedagogical revolution is needed to improve the quality of learning because teaching in most Arab states continues to be highly didactic, teacher-directed, and not conducive to fostering analytical or critical thinking. As pointed out by Whitaker (2009), if this makes young Arabs well equipped for anything at all, it is how to survive in an authoritarian system: just memorize the teacher's words, regurgitate them as your own, avoid asking questions – and you will stay out of trouble. In the same way, the suppression of the critical faculties of the students turns some of them into gullible recipients for religious ideas that would collapse under serious scrutiny while making them ill equipped for roles as active citizens and contributors to their countries' development.

Despite the inability of Arab education to develop critical thinking among young people, the year 2011 saw the mobilization of youth to challenge many ossified political powers. The contribution of information and communication

technology including social networks has been crucial. Now, as large parts of the Arab world (Bahrain, Syria, Egypt, Yemen, Libya, and Tunisia) start the long process of democratization, a self-evident but often ignored fact is that democracy will thrive only in a culture that accepts diversity, respects different points of view, regards truths as relative rather than absolute, and tolerates – even encourages – dissent thinking. Schools hold particular responsibility on this issue.

Youth Employment, Minority Languages, and Religious Education

The issue of youth employment, minority languages, and religious education will guide the possibilities of improving educational systems in the region over the coming decades.

Education is often suggested as a solution to unemployment, but in MENA, educated youth are often less likely to be employed than the less educated. For example, in Egypt, those with the lowest education have the lowest unemployment (El-Hamidi and Wahba, 2006).

Current youth unemployment levels in the region are approximately 25%. First-time job seekers, mostly between 15 and 24 years of age, make up more than 50% of the unemployed – the highest regional average worldwide. Young people with secondary and postsecondary education face special challenges. The average duration of unemployment for youth with university or vocational education is relatively high. In Morocco, it is 3 years and in Egypt, it is two and a half. In the past, a secondary school degree made graduates eligible for a public sector job with lifetime security and social protection. Today, secondary degrees are at best guarantors of an informal wage job, demonstrating a dramatic devaluation of educational credentials and, as a result, tremendous dissatisfaction among the educated (Dhillon and Yousef, 2007).

In the twenty-first century, a typical youth in the Middle East spends an average of 8 years being educated, followed by a period of unemployment, or 'wait-hood,' which can last several years. During this period, however, pathways to independent life become unpredictable and inaccessible (Dhillon and Yousef, 2007).

Singerman (2007) argues that "the consequences of the youth bulge in the region can only be fully understood by an examination of the political economy of youth through the lens of the 'marriage imperative'." Economists speak of the phenomenon of 'wait unemployment,' of enduring long periods of unemployment in order to secure a high paying 'permanent' position with good benefits. In a similar vein, many young people in Egypt, and throughout the region, experience 'wait adulthood' or 'wait-hood' as they negotiate their prolonged adolescence and remain single for long periods of time while trying to save money for marriage. The author argues that there has been silence around the economic dynamics of marriage. Thus, many youth and parental attitudes and decisions, as well as policy interventions surrounding the school-to-work transition, make little sense without incorporating marriage into the equation. Policy makers must, therefore, consider the school-to-work-to-marriage transition when designing strategies to improve the lives of young people.

It is important to emphasize that the issue of lack of employment cannot be solved simply by schooling or education. At the same time, it is necessary that the economy of the region can be more dynamic in terms of job creation. Therefore, it is the overall development strategy that must be revised entirely if one hopes to find a solution to the problem of youth unemployment.

For decades, the main linguistic and ethnic minorities in the region had no right to use their language in schools. However, the two main linguistic minorities (Tamazight and Kurds) have seen their language rights improve during the last decade.

Until recently in Morocco, Berber languages, such as Tamazight, were not used formally in school and were only used in informal settings in areas where people considered themselves ethnically Berber:

> After independence, Berber was excluded from schools in the name of state-building and in search of a unified national identity. This forced a whole generation of children to enter school in a language they had never spoken before, contributing to a higher dropout rate among Berber children. Trouble for Berber-only speakers did not stop in the educational system. Many continued to face other difficulties communicating in hospitals and the court system, where Arabic and French dominated.
>
> Ennaji, 2009: p. 19

In the year 2000, King Mohammed VI established the National Charter of Education and Training, providing for reforms in the area of education. The Charter acknowledges the existence of Morocco's linguistic issues in Act 9, Article 110, where the stated goal is to strengthen the teaching and use of the Arabic language, empower foreign languages, and be open to the teaching of Tamazight (Daniel and Ball, 2009). In 2007, nearly 300 000 students – native Arabic speakers as well as Berber speakers – were enrolled in Berber courses, according to the Ministry of Education (Errihani, 2008).

In Iraq, article 34 of the Constitution of 2005 stipulates that education is a fundamental factor for the progress of society and is a right guaranteed by the State. Article 4 specifies that the Arabic language and the Kurdish language are the two official languages of Iraq. The right of Iraqis to educate their children in their mother tongue, such as Turkmen, Assyrian, and Armenian, shall be guaranteed in government educational institutions (UNESCO-IBE, 2011). Today, Kurdish children in Kurdistan Iraq are taught Kurdish as their means of instruction in all subjects (Taylor and Skutnabb-Kangas, 2009).

The question of religious education arises at several levels in the MENA region. First, because of the religious origin of traditional educational institutions before colonization, religion is present in schools. Some reports point to the importance of the amount of time devoted to religion compared to other subjects and compared to the situation in other developing countries. Primary schools in Saudi Arabia devote 31% of the classroom time to religion (Rivard and Amadio, 2003), compared with just 20% of time allotted to mathematics and science. Furthermore, research has shown that the time spent on academic tasks is one of the key factors in learning outcomes. In fact, if the countries of the region want to improve their performance in international comparative studies, they must reflect on the time allocated for each subject including religion.

Another more controversial issue in religious education is related to the content of this teaching. Groiss (2003) focused

on the biased attitude that Saudi Islamic education textbooks construct about topics such as Judaism and Christianity, Western civilization and imperialism more generally, and the way certain historical events such as the Crusades and the Palestinian struggle are taught. Yet, as rightly suggested by Labidi (2010), Groiss addresses with great simplicity the complex issues that lie beneath the question of Western representation. The relationship between the West and the Arab World are shaped by complex colonial, geopolitical, and historical factors.

> In order to improve Arab education, mutually deconstruct Arab/Muslim and Western stereotypes, diffuse the tension between the West and Arab populations, and put both sides on better grounds of negotiation, over simplifications, inaccuracies, distortions, and de-contextualizations of certain facts ought to be addressed. Teaching a selective and sanitized history that centers on oppression, silence, and denial leads to ignorance and naïve judgments.
>
> Labidi, 2010: p. 213

Conclusion

Education in the MENA region has undergone vast changes in recent decades. Access to school, which was limited in the aftermath of independence, has now become the rule for most Arab children. However, this quantitative leap has not been followed by the desired effect. Not only the quality of young Arabs' learning, which is not well rated by international standards, but also the expected benefits of schooling, have been slow to materialize. The unemployment rate for graduates is even higher than for those who did not attend school. Structural changes are urgent. Educational governance of the education systems of the countries of the region is inevitable. Consequently, reform of the teaching profession should be a top priority.

Abstract

Defining the concept of skills can be somewhat problematic. The term is basically an Anglo-Saxon one derived from the structure of jobs in the labor market. Other countries from around the world avoid the term skills, preferring instead the notion of occupations and/or competencies. In this article, I will explore these tensions in how skills are defined and measured in different economies. This will involve examining the distinctions between generic and basic skills and how skills are acquired and utilized. Finally, the links between qualifications and skills will be explored with reference to National Qualification Frameworks and skills training in initial and continuing vocational education systems.

Defining the concept of skill is notoriously difficult. The term is based upon the notion of a cluster of activities surrounding a job. The actual dictionary definition refers to ability, forte, gift, strength, and/or know-how. There is also a suggestion that it involves a judgment of competence. They can be referred to as hard and soft skills, generic skills, and basic skills. Indeed, in many ways the "concept of skill has become bigger, broader and much fuzzier around the edges" (Warhurst et al., 2004: p. 14). The article will provide a general introduction to the notion of skills, one that problematizes the concept and sets it within different cultural contexts. It will be argued that skills are difficult to define and measure. However, it will also be acknowledged that they have become much more important in the labor market and consequently within education and training systems around the world.

Defining Skills

The notion of 'skills' can really only be understood within a context, that context being the vocational education and training system of the country in question. There is, in other words, a strong cultural imperative that underpins the notion of skills. For instance in Anglo/Saxon countries, skills are often defined very narrowly:

> A skill is a specific ability of an individual, typically manual and/or coordinative features, which is geared to a task – or, more precisely, a task type – itself quite a narrow category, involving the application of a technique.
>
> Winch, 2011: p. 88

They are to be found within jobs in the workplace and are essentially individual rather than collective activities. They can also be measured by proxy through qualifications and classified into occupational groupings to determine how they will change over time.

However, in other countries the term skill is often avoided. In Germany the concept of *Beruf* is preferred, denoting an occupational identity and status. It is concerned with the individual acting in a certain socially defined role that has been arrived at through negotiations with social partners (Brockmann et al., 2011). This is a much broader concept than skills and forms the basis of the much admired Dual System of work-based education for intermediate occupations. In France the VET system is underpinned by the concept of *savoir*, meaning a body of knowledge. Although knowledge in action is important, savoir-faire, vocational formation is primarily concerned with acquiring and mastering knowledge (Méhaut, 2011).

One of the main determinants of how skills are conceptualized is the context within which they are situated. Anglo-Saxon countries will tend to locate skills within the individual and measure them through employer's allocated jobs in the workplace. Alternatively, in countries with a long history of social partnerships, skills will only form part of an overall framework based upon occupations and a collective sense of social division and citizenship.

Within the European Union the concept of *competence* has become an overarching term for denoting capability. Interestingly, competence is not defined narrowly within this context. Rather it includes the notions of autonomy and responsibility and incorporates both skills and knowledge requirements. This broader and more integrated concept of competence is used within the European Qualification Framework (EQF). However, the notion of competence is difficult to quantify and is rarely used when measuring skills.

Generic and Basic Skills Training

Within the policy-making discourse, generic skills are generally taken to mean a set of discrete clusters of skills, normally at a foundation level, that are transferable across different work contexts. They are usually distinguished from basic skills and, it is claimed, can be identified and assessed at varying levels of ability. Although these clusters of skills change over time, they have become increasingly identified with the work-based practices of communication, working with others, numeracy, problem solving, and information technology. The theoretical argument in support of the concept of generic skills rests mainly on the twin ideas that skill sets reside within the individual and are transferable

across boundaries. This notion of a 'transporting' phenomenon seems intuitive enough, particularly when applied to contexts that are identical in nature. The theoretical arguments underpinning generic skills have, however, come under criticism in recent years. Firstly, the notion of 'transfer' has been seen to be highly problematic. There is little convincing evidence to support the argument that skills can be transported across contexts even at the most rudimentary of levels (Cree et al., 1998). The idea that skills are not easily transferred across contexts may seem, at first glance, to be somewhat counter-intuitive. However, it is difficult to identify even basic replicative knowledge that is transportable in this manner. The suggestion that more complex skills are, somehow, embedded within an individual and automatically transferred across a range of contexts remains highly implausible. Indeed, the concept of 'transfer' is probably better understood as a 'metaphorical' discourse than an empirical phenomenon.

One of the most heated debates around the notion of skills is that of basic skills or foundation skills. In most countries this often refers to literacy and numeracy skills. However, other 'softer' skills are now being included under this heading. For instance, communication skills, teamwork, and information technology are recognized as essential skills. Most education systems acknowledge that these skills are required before progressing on to a broader academic or vocational curriculum. However, not everyone agrees on how to teach basic skills. Recent research has tended to contextualize our understanding of foundation skills within a broader context (Barton et al., 2000). Here literacies are viewed as part of social practices and learned through interactions between 'real texts and the associated practices with their use.'

Skill Acquisition and Utilization

Generally speaking, the policy rhetoric on skills tends to prioritize skill acquisition over skill utilization. In initial vocational education and training the emphasis is on acquiring skills in order to compete in the labor market. This can refer to entry level skills for young people and/or returners to the workforce following a period of unemployment. Governments from across the world have also tended to set challenging targets for the level of skills held by their workforce. Most claim to be pursuing a 'high-skill' policy agenda, although in practice Anglo-Saxon labor markets seem to exhibit more of an 'hour glass' phenomenon with a combination of high and low skills and a squeezed middle of intermediate skills. Indeed, even this squeezed middle remains problematic as the emerging 'sunrise' associate professional and technical occupations are growing in number against a backdrop of a decline in the 'sunset'-skilled trades. In comparison, less attention has been paid to how skills are utilized (Keep and Mayhew, 2001). There are of course ongoing debates on the implications of an 'over-educated' workforce given the number of graduates entering the labor market. However, far less attention has been paid to the 'overworked' population and the shifting patterns of employment and occupations within current skill-sets.

Measuring Skills

How are skills measured? Most national frameworks for measuring skills are informed by the International Standard Classification of Occupations, ISCO-883. For instance in the United Kingdom the Standard Occupational Classification structure (SOC) is based on two main concepts: the concept of the kind of work performed or 'job' and the concept of 'skill.' Of these two concepts, that of a 'job' is well recognized. However, skills can be more problematic:

> The concept of skill is widely used, but it not defined or regulated in a consistent fashion. For classification purposes, skill is defined as the ability to carry out the tasks and duties of a job in a competent, thorough and efficient manner. Two aspects of this definition of skill are distinguished in the SOC: *skill level* is defined in terms of complexity of the tasks and duties to be performed; *skill specialisation* is defined as the field of knowledge required for competent, thorough and efficient conduct of the tasks.
>
> Anderson, 2009

Within the ISCO, four skill levels are broadly defined. Interestingly, the measurement of skills using the standard classification allows us to identify and explore the changing patterns of occupations and employment. This is a particularly valuable aspect of the categorization process as it allows us to see how jobs change over time. What is striking here is how occupations and jobs emerge and disappear, historically speaking, in relatively short time periods. In some countries these shifts are quite dramatic, while in others labor markets are more stable. How a country competes internationally can often be ascertained through shifting occupational structures and the rapidly changing nature of jobs in the economy.

Qualifications and Skills Training

Qualifications tend to act as a proxy for skills. This is the case within the OECD and the European Union. A recent trend has been to encourage the establishment of National Qualifications Frameworks (NQFs) in order to facilitate the transfer of skills across nation-states. The EQF for instance sets out to establish equivalences of qualifications based upon different levels of academic and vocational achievement. These levels (eight in total) are, in turn, matched with three separately identified components of ability: knowledge, skills, and competence. This 'metalevel' framework then acts as a benchmark for comparison with individual countries' own NQFs. These frameworks have been developed elsewhere in the world, most notably in Australia, New Zealand, and South Africa. There has also been an attempt to standardize individual qualifications using the concepts of learning outcomes and competencies. The former is based upon what is notionally required of an experienced worker in terms of knowledge and skills as a result of undertaking a recognized qualification. The competency element relates to the type of skill required (e.g., hard and soft skills) and the knowledge necessary to carry out the task successfully and is an indicator of the degree of autonomy and responsibility exercised by the worker.

Skills training can be categorized as initial vocational education and training or continuing vocational education and training. Initial vocational training can either be work-based or work-related. Many European countries have vocational training as part of their upper-school curriculum, often combined with liberal studies. This normally involves an element of work placement activities and attendance at a school or college. However, a number of countries operate a work-based apprenticeship model, e.g., Germany, Austria, and Switzerland. There has been a renewed interest in modern apprenticeships for younger and older workers, typically to be found in the new service sectors. Interestingly, the gender balance is also shifting, with the majority of new apprentices being women. Nonetheless, apprenticeships still account for a small proportion of the number of occupations in many countries. In fact work-related skills are more often than not taught in colleges of further education or increasingly within Higher Education. Continuing provisional education and training normally takes place in organizations and workplaces. It is typically informal and unaccredited and concentrated amongst younger and newer employees. Most labor market studies indicate that access to continuing education and training at work is highly gendered and based upon occupational status and previous educational attainment.

Educational Effectiveness Theory and Research: Recent Advances

Leonidas Kyriakides, University of Cyprus, Nicosia, Cyprus

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides a critical analysis of the main approaches to modeling educational effectiveness (economic, psychological, and sociological). During the 1990s an integrated approach to modeling effectiveness has been developed. Studies testing the validity of multilevel models emerged from this approach reveal the importance of considering the dynamic nature of education. Thus, a dynamic model of educational effectiveness has been developed. The main characteristics of this model and findings of studies providing support to its validity are presented. Finally, the importance of investigating the extent to which the dynamic model can be used for school improvement purposes is stressed.

Introduction

Educational effectiveness research (EER) addresses the question what works in education and why. EER has expanded rapidly during the last three decades. Methodological advances have enabled more efficient estimates of teacher and school differences in student achievement to be obtained. In regard to the theoretical component of the field, progress was made by a more precise definition of the concepts used and the relations between the concepts (Scheerens and Bosker, 1997). However, there is a shortage of rational models from which researchers can build theory. The problem is aggravated by infrequent use of whatever models exist (Kyriakides, 2005). As a consequence, most effectiveness studies are concerned with the establishment of statistical relationships between variables rather than with the generation and testing of theories which could explain those relationships.

In this article, a critical analysis of current approaches to modeling educational effectiveness is provided and the importance of considering the dynamic nature of educational effectiveness is stressed. It is argued that the dynamic model of educational effectiveness (Creemers and Kyriakides, 2008), which has recently been developed in order to address the weaknesses of the integrated models, could contribute in establishing a theory-driven and evidence-based approach to school improvement. Thus, the essential characteristics of the dynamic model are presented and the main findings of studies testing the validity of the model are outlined. Finally, suggestions for research in order to develop the theoretical framework of EER are drawn.

A Critical Analysis of the Models of EER

In the literature of educational effectiveness modeling, three basic approaches have been used. First, the economic approach is focused on estimating the relationship between the "supply of selected purchased schooling inputs and educational outcomes controlling for the influence of various background features" (Monk, 1992: p. 308). Resource input variables such as student/teacher ratio, teacher salary and overall measures of per student expenditure were of primary interest in the earlier studies. The emerging 'education production' models (e.g., Brown and Saks, 1986; Coates, 2003; Elberts and Stone, 1988) are based on the assumption that increased inputs will lead to increments in outcomes and their main characteristics are concerned with (1) the selection of resource inputs as the major type of selection of antecedent condition, (2) the measurement of direct effects, and (3) the use of data at only one level of aggregation (i.e., either at micro (e.g., student) level or aggregated (e.g., school) level). However, the research done using these models revealed that the relation between input and outcomes is more complex than was assumed. For example, studies from Hanushek and Hedges (e.g., Hanushek, 1986, 1989; Hedges et al., 1994) show that reducing student/teacher ratio and/or increasing the amount of funding education per student does not necessarily result in higher student outcomes.

The second approach to effectiveness modeling is similar to the economic approach but is focused on a different choice of antecedent conditions since it is mainly focused on variables at student level which are assumed to predict student outcomes. Some attention is also paid on processes from two different perspectives concerning learning and school as organizations. Within this approach, educational psychologists focused on student background factors such as 'learning aptitudes,' 'personality,' and 'motivation' and on variables measuring the learning processes which take place in classrooms. On the other hand, the sociological perspective is focused on factors that define the educational background of students such as socio-economic status, gender, social-capital, and peer group. This perspective does not only examine student outcomes, but also the extent to which schools manage to reduce the variance in student outcomes compared to prior achievement. In this respect, studies on the effects of contextual factors (Opdenakker and Van Damme, 2006) and on the extent to which teachers and schools are equally effective with different groups of students (i.e., differential school effectiveness) have been conducted (e.g., Campbell et al., 2004; Strand, 2010). Moreover, the sociological perspective raises attention for process variables emerged from organizational theories which were treated as school-level factors associated with student achievement (Scheerens, 2013).

Finally, the models of the third approach emerged by researchers attempt to integrate the findings of school effectiveness research, teacher effectiveness research, and the early

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92102-0

input–output studies. Thus, the models of this approach (e.g., Creemers, 1994; Scheerens, 1992; Stringfield and Slavin, 1992) have a multilevel structure, where schools are nested in contexts, classrooms are nested in schools, and students are nested in classrooms or teachers. Although these models make use of both organizational theories and theories of learning and refer to multiple factors at different levels, each of them is either focused on the classroom or the school level. Depending on this, more emphasis is given either to theories of learning (e.g., Creemers, 1994) or to organizational theories (e.g., Scheerens, 1992).

The comprehensive model of educational effectiveness (Creemers, 1994) is considered as one of the most influential models in the field (Teddlie and Reynolds, 2000). Creemers' model is based on four assumptions. First, time-on-task and opportunity used at the student level are directly related to student achievement. Second, quality of teaching, the curriculum, and the grouping procedures influence the time on task and opportunity to learn. For example, some teachers spend more time actually teaching than others who spend more time on classroom management and keeping order. Teachers are, therefore, the central component in instruction at the classroom level. Third, teaching quality, time, and opportunity at the classroom level are influenced by factors at the school level that may or may not promote these classroom factors. Thus, quality, time, and opportunity are not the key concepts at the classroom level only, but also at the school level.

Six studies examined the validity of Creemers' model and provided some empirical support to the model (Kyriakides, 2008). These studies revealed that the influences on student achievement are multilevel. This finding is in line with the findings of most effectiveness studies (Teddlie and Reynolds, 2000) and provides support to the argument that the theoretical models of EER should be multilevel in nature. However, the analyses of the results of these studies also revealed that next to the multilevel nature of effectiveness the relationship between factors at different levels might be more complex than assumed in the integrated models. This is especially true for interaction effects among factors operating at classroom and student level which reveal the importance of investigating differential effectiveness (Campbell et al., 2004). A synthesis of these studies has also revealed suggestions for further development of the model, especially by taking into account the dynamic nature of educational effectiveness (Kyriakides, 2008). Teaching and learning are dynamic processes that are constantly adapting to changing needs and opportunities. Effective schooling should, therefore, be treated as a dynamic, ongoing process. This idea is also consistent with the contingency theory (Donaldson, 2001; Mintzberg, 1979). In this context, Creemers and Kyriakides (2008) have developed a dynamic model of educational effectiveness which attempts to define the dynamic relations between the multiple factors found to be associated with student achievement.

The Dynamic Model of Educational Effectiveness: An Overview

The dynamic model is based on the following three main assumptions. First, the fact that most of the effectiveness studies are exclusively focused on language or mathematics rather than on the whole school curriculum aims (cognitive, metacognitive, and affective) reveals that the models of EER should take into account the new goals of education and related to this their implications for teaching and learning. This means that the outcome measures should be defined in a more broad way rather than restricting to the achievement of basic skills. It also implies that new theories of teaching and learning are used in order to specify variables associated with the quality of teaching. Second, an important constraint of the existing approaches of modeling educational effectiveness is the fact that the whole process does not contribute significantly to the improvement of school effectiveness. Thus, the dynamic model is established in a way that helps policy makers and practitioners to improve educational practice by taking rational decisions concerning the optimal fit of the factors within the model and the present situation in the schools or educational systems. Finally, the dynamic model should not only be parsimonious but should also be able to describe the complex nature of educational effectiveness. This implies that the model could be based on specific theory, but at the same time some of the factors included in the major constructs of the model are expected to be interrelated within and/or between levels.

The main characteristics of the dynamic model are as follows. First, the dynamic model is multilevel in nature and refers to factors operating at the four levels shown in **Figure 1**. Teaching and learning situation is emphasized and the roles of the two main actors (i.e., teacher and student) are analyzed. Above these two levels, the dynamic model refers to school-level factors which are expected to influence the teaching–learning situation by developing and evaluating the school policy on teaching and the policy on creating the School Learning Environment (SLE). The system level refers to the influence of the educational system through a more formal way, especially through developing and evaluating the educational policy at the national/regional level. The teaching and learning situation is also influenced by the wider educational context in which students, teachers, and schools operate. Factors such as the values of the society for learning and the importance attached to education play an important role both in shaping teacher and student expectations as well as in the development of the perceptions of various stakeholders about effective teaching practice.

Second, the dynamic model supports that factors at the school and system level have both direct and indirect effects on student achievement since they are able to influence not only student achievement but also the teaching and learning situations. Third, the model assumes that the impact of the school- and system-level factors has to be defined and measured in a different way than the impact of classroom-level factors. Policy on teaching and actions taken to improve teaching practice must be measured over time and in relation to the weaknesses that occur in a school. The assumption is that schools and educational systems, which are able to identify their weaknesses and develop a policy on aspects associated with teaching and their SLE, are also able to improve the functioning of classroom-level factors and their effectiveness status. Only changes in those factors for which schools face significant problems are expected to be associated with the improvement of school effectiveness. This implies that the

Figure 1 The dynamic model of educational effectiveness.

impact of school- and system-level factors depends on the current situation of the objects under investigation.

Fourth, the model assumes that there is a need to carefully examine the relationships between the various effectiveness factors which operate at the same level. Walberg's (1984) model, which is one of the most significant educational productivity models, attempts to illustrate such relationships. Aptitude, instruction, and the psychological environment are seen as major direct causes of learning. They also influence one another and are in turn influenced by feedback on the amount of learning that takes place. The Walberg's model was tested as a structural equation model on science achievement, indicating more complex, indirect relationships (Reynolds and Walberg, 1990). This implies that there is a need to refer to the relationships between the effectiveness factors which operate at the same level. Such approach to modeling educational effectiveness may reveal grouping of factors that make teachers and schools effective. Therefore, strategies for improving effectiveness which are comprehensive in nature may emerge.

Finally, the dynamic model is based on the assumption that each factor can be defined and measured by using five dimensions: *frequency*, *focus*, *stage*, *quality*, and *differentiation*. *Frequency* is a quantitative way to measure the functioning of each effectiveness factor whereas the other four dimensions examine qualitative characteristics of the functioning of each factor at the system/school/classroom level. A brief description of the four dimensions concerned with the qualitative characteristics of effectiveness factors is given below.

Two aspects of the *focus* dimension are taken into account. The first one refers to the specificity of the activities associated with the functioning of the factor whereas the second one to the number of purposes for which an activity takes place. The

measurement of the focus of an activity, either in terms of its specificity or in terms of the number of purposes that it is expected to achieve, may be related in a nonlinear way with student achievement. For example, guidelines on parental involvement which are very general may not be helpful at all in establishing good relations between parents and teachers, which, when good, can result in supporting student learning. On the other hand, a school policy which is very specific in defining activities may restrict teachers and parents from being productively involved and creating their own ways for implementing the school policy. The *stage* at which tasks associated with a factor take place is also examined. Factors need to take place over a long period of time to ensure that they have a continuous direct or indirect effect on student learning. The *quality* refers to the properties of the specific factor itself, as these are discussed in the literature. Finally, *differentiation* refers to the extent to which activities associated with a factor are implemented in the same way for all the subjects involved with it (e.g., all the students, teachers, schools). It is expected that adaptation to specific needs of each subject or group of subjects will increase the successful implementation of a factor and will ultimately maximize its effect on student learning outcomes. The use of different measurement dimensions reveals that looking at just the frequency of an effectiveness factor does not help us identify those aspects of the functioning of a factor which are associated to student achievement. Considering effectiveness factors as multidimensional constructs not only provides a better picture of what makes teachers and schools effective but may also help us develop specific strategies for improving educational practice.

Based on the main findings of teacher effectiveness research (e.g., Brophy and Good, 1986; Muijs and Reynolds, 2001; Rosenshine and Stevens, 1986), the dynamic model refers to factors which describe teachers' instructional role and are associated with student outcomes. These factors refer to observable instructional behavior of teachers in the classroom rather than on factors that may explain such behavior (e.g., teacher beliefs and knowledge and interpersonal competences). The eight factors included in the model are as follows: orientation, structuring, questioning, teaching-modeling, application, management of time, teacher role in making classroom a learning environment, and *classroom assessment*. These eight factors do not refer only to one approach of teaching such as structured or direct teaching (Joyce et al., 2000) or to approaches associated with constructivism (Schoenfeld, 1998). An integrated approach in defining quality of teaching is adopted.

In regard to the school factors, the dynamic model gives emphasis to the following two main aspects of the school policy which affect learning at both the level of students and teachers: (1) *school policy for teaching* and (2) *school policy for creating a learning environment at school*. Guidelines are seen as one of the main indications of school policy and this is reflected in the way each school-level factor is defined. However, in using the term guidelines we refer to a range of documents, such as staff meeting minutes, announcements, and action plans, which make the policy of the school more concrete to the teachers and other stakeholders. These two factors do not imply that each school should simply develop formal documents to install its policy. The factors concerned with the school policy mainly refer to the actions taken by the school to help teachers and other stakeholders have a clear understanding of what is expected from them to do. Support offered to teachers and other stakeholders to implement the school policy is also an aspect of these two school factors.

Based on the assumption that the essence of a successful organization in the modern world is the search for improvement, the dynamic model is also concerned with the processes and the activities which take place in the school in order to improve the teaching practice and its learning environment. For this reason, the processes which are used to evaluate the school policy for teaching and the SLE are investigated. Thus, the following four overarching factors at the school level are included in the model:

1. school policy for teaching and actions taken for improving teaching practice,
2. evaluation of school policy for teaching and of actions taken to improve teaching,
3. policy for creating an SLE and actions taken for improving the SLE, and
4. evaluation of the SLE.

Testing the Validity of the Dynamic Model

Some supportive material for the validity of the dynamic model has been provided. Specifically, a longitudinal study measuring teacher and school effectiveness in three different subjects (i.e., mathematics, language, and religious education) was conducted in order to test the main assumptions of the model. Using Structural Equation Modeling (SEM) techniques, it was possible to demonstrate that classroom and school factors can be defined by reference to the five dimensions of the dynamic model (Kyriakides and Creemers, 2008). The added value of using these five dimensions of the classroom and school level factors to explain variation on student achievement in both cognitive and affective outcomes of schooling was also demonstrated. Finally, it was possible to generate evidence supporting the assumption that the impact of school factors depends on the current situation of the school and on the type of problems/difficulties that the school is facing. Specifically, school factors were found to have situational effects. The development and evaluation of a school policy for teaching were found to have stronger effects in schools where the quality of teaching at classroom level was low (Creemers and Kyriakides, 2009).

Second, a study investigating the impact of teacher factors on achievement of students at the end of preprimary school was conducted (Kyriakides and Creemers, 2009). By comparing the results of this study with the findings of the first study testing the validity of the model, it was shown that almost all teacher factors were associated with achievement in language and mathematics at both phases of schooling (see Kyriakides and Creemers, 2009). Some factors were also found to be more important for one age of schooling indicating the possibility of having differential effects. For the purpose of testing the generic nature of the model, this difference does not question the importance of teacher factors within the model. These differences in effect sizes might be attributed to

differences in the developmental stages of the two groups of students and related to that to the functioning and the curriculum of each phase of schooling.

Third, the validity of the dynamic model at the school level was supported by the results of a quantitative synthesis of 67 studies exploring the impact of school factors on student achievement (Kyriakides et al., 2010). This meta-analysis revealed that effective schools are able to develop policies and take actions in order to improve their teaching practice and their learning environment. Factors excluded from the dynamic model were found to be weakly associated with student achievement.

Finally, a follow-up study testing the validity of the dynamic model was conducted (Creemers and Kyriakides, 2010). The methods used were identical to those followed by the original study testing the validity of the model. This study provided support to the generalizability of the original study. Very similar results on the impact of teacher and school factors upon student achievement emerged from both the original and the follow-up study. Since the follow-up study took place in the same schools where the original study took place, changes in the effectiveness status of schools and in the functioning of effectiveness factors were also identified. Discriminant function analysis reveals that changes in the functioning of school factors can help us classify the schools into those which improved their effectiveness status or remained equally effective or even reduced their effectiveness status (see Creemers and Kyriakides, 2010). Thus, this study was able to test one of the essential differences of the dynamic model which has to do with its attempt to relate changes in the effectiveness status of schools to the changes in the functioning of school factors.

Conclusions and Suggestions for Further Research

In this article, it is demonstrated that useful contributions were already being made in the area of theory in 1990s but there is a need to take them further. Studies testing the validity of the comprehensive model revealed that the variation in 'what worked,' if it could be explained and theoretically modeled, would force the field toward the development of more complex and multifaceted accounts than the 'one size fits all' mentality that had hitherto existed in the field during the 1990s. In this context, the dynamic model of educational effectiveness has been developed. This model attempts to illustrate the complex and dynamic nature of educational effectiveness and takes into account the findings of research on differential effectiveness (Scheerens, 2013). In this article, the dynamic model is outlined and studies supporting the validity of the model are briefly presented. Since the dynamic model was designed in order to establish stronger links between EER and improvement of practice, experimental studies and/or case studies are currently being conducted to identify the extent to which schools can make use of the dynamic model for improvement purposes (see Creemers and Kyriakides, 2012). These studies may help us identify when and under what conditions schools can make use of the dynamic model and establish an evidence-based and theory-driven approach to school improvement.

Abstract

This article provides a historical review of Educational Effectiveness Research (EER). Four sequential phases in the field which address different types of research questions and promote the theoretical development of educational effectiveness are identified. It is shown that research on effectiveness moved from investigating the extent to which teachers and schools influence learning outcomes to establishing theoretical models which refer to the complexity and the dynamic nature of education. Methodological developments that promoted the development and testing of the theoretical framework of EER are also presented. Thus, the knowledge base of EER is currently used for establishing an evidence-base and theory-driven approach to promote quality in education.

Introduction

Educational Effectiveness Research (EER) can be seen as an overarching theme that links together a conglomerate of research in different areas, including research on teacher behavior and its impacts, curriculum, student grouping procedures, school organization, and educational policy. The main research question underlying EER is the identification and investigation of which factors in the teaching, curriculum, and learning environments (operating at different levels such as the classroom, the school, and above-school) can directly or indirectly explain measured differences (variations) in the outcomes of students. Further, such research frequently takes into account the influence of other important background characteristics, such as student ability, socioeconomic status (SES), and prior attainment. Thus, EER attempts to establish and test theories which explain why and how some schools and teachers are more effective than others in promoting better outcomes for students. However, it is also important to note that the three terms – school effectiveness, teacher effectiveness, and educational effectiveness – are used inconsistently in the literature and that these are themselves interrelated. In this article, school effectiveness is taken to mean the impact that school-wide factors, such as a school policy for teaching, school climate, and the 'mission' of a school, have on students' cognitive and affective performance. On the other hand, teacher effectiveness is taken to mean the impact that classroom factors have on student performance, and includes teacher behavior, teacher expectations, classroom organization, and use of classroom resources. Teddlie (1994) argued that most teacher effectiveness studies have been concerned with only the processes that occur within classrooms to the exclusion of school-wide factors, whereas most school effectiveness studies have involved phenomena that occur throughout the school with little emphasis on particular teaching behaviors within individual classrooms. This weakness has begun to be addressed in studies conducted during the last three decades. The attempts to deal with both teacher and school influences can be seen as a significant development in EER since joint studies on school and teacher effectiveness reveal that neither level can be adequately studied without considering the other. In this context, we are using the term educational effectiveness rather than teacher and/or school effectiveness to emphasize the importance of conducting joint school and teacher effectiveness research which can help us identify interactions between the school, classroom, and student levels and their contributions in explaining variation in students' outcomes, both academic and noncognitive. Finally, it is important to note that EER also refers to the functioning of the educational system as a whole, and this research can therefore also be used to support the development and testing of different models of effectiveness. In turn, these models of effectiveness ultimately attempt to explain why educational systems and their subcomponents perform differently, toward the aim of providing relevant evidence for policy makers.

In this context, this article provides a historical review of educational effectiveness. This article helps readers identify the theoretical and methodological progress that the field managed to make during the last decades. It is shown that studies conducted in various countries managed to contribute to the development and testing of complex and dynamic theories of effectiveness. In the last part of this article, we discuss how the knowledge base of EER can be used to establish an evidence-based and theory-driven approach to school improvement and refer to experimental studies searching for the impact of such an approach in promoting student learning outcomes.

Historical Review of Educational Effectiveness

The origins of EER stem from reactions to the work on equality of opportunity undertaken by Coleman et al. (1966) and Jencks et al. (1972). The first two effectiveness studies undertaken, independently, by Edmonds (1979) and Rutter et al. (1979) during the 1970s were concerned with examining evidence and making an argument about the potential power of schooling to make a difference in students' life chances. This was an optimistic point of view because many studies published in that period showed that teachers, schools, and maybe even education in general did not make much of a difference at all. The early existence of two independent research projects in different countries asking similar questions and drawing, to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92101-9

a certain extent, on similar quantitative methodologies demonstrated the potential for establishing a scientific domain dealing with effectiveness in education (Creemers et al., 2010). Thus, the publications by Brookover et al. (1979) and Rutter et al. (1979) were followed by numerous studies in different countries on educational effectiveness and the development of international interest and collaboration through the creation of the International Congress for School Effectiveness and Improvement in 1990 (Teddlie and Reynolds, 2000). Looking at the history of EER, we see four sequential phases in the field which address different types of research questions and promote the theoretical development of EER.

First Phase: Establishing the Field by Showing That Teachers and Schools Matter

The studies of the first phase of EER were mainly concerned with revealing that teachers and schools differ among themselves in their impact on student performance and thereby that student progress in part depends on who is their teacher and which school they attend. The extent to which schools differ was the next question raised by researchers in the field with a more precise version concerning how much schools differ in terms of student outcomes when they are more or less equal in terms of the innate abilities and socioeconomic background of their students (using statistical controls for variations in student intake characteristics). EER aimed to make fair comparisons between teachers and schools in order to assess the impact of schooling on student achievement that can be uniquely attributed to, for example, teacher A or school X, rather teacher B or school Y. Such research was enabled through the use of multilevel models that allowed for clustering of the data at the teacher (class) and at the school level which enabled more precise estimates of variation between schools and the identification of individual school effects (through residual estimates and their associated confidence limits). By the end of this phase, a clear message about the important role of teachers and schools had emerged from a large number of studies conducted in various countries and these provided a strong argument against critics who had argued that teachers and schools did not matter for student outcomes. However, the issue of educational effectiveness did not end by assessing the differences between schools and teachers in terms of their effectiveness. Rather, this was merely a prelude to exploring what matters in schools. In this context, the so-called 'five-factor model' (Edmonds, 1979) was presented which was based on outlier and correlation studies. This initial model has since been criticized on methodological and also conceptual grounds. But it has an impact on moving the field from the question whether teacher and/or school matters to the identification of factors that may be related with student outcomes, as is demonstrated below.

Second Phase: Searching for Factors Associated with Student Outcomes

The main research question of the second phase of EER refers to identifying those factors that help to explain differences in the effectiveness of teachers and schools. The results of studies conducted during this phase produced lists of correlates that were associated with better student achievement and which were treated as key effectiveness factors. A review of the results of the studies conducted during this phase (Levine and Lezotte, 1990; Sammons et al., 1995) resulted in numerous correlates for effective classrooms, schools, and above-school levels (districts, states, country). Together, these studies emphasized once more the importance of further developing the relatively limited theoretical foundation of EER by including the combination of correlates into categories.

Third Phase: Development of Theoretical Models

The third phase of EER saw researchers use several theoretical orientations to help explain why certain characteristics might contribute to educational effectiveness (Scheerens and Bosker, 1997). Generally speaking, there are three perspectives within EER in this phase which attempted to explain why and how certain characteristics contribute to educational effectiveness, and relevant theoretical models emerged from these approaches. These perspectives stem from economics, psychology, and sociology of education and are described in the article Theory of Educational Effectiveness (*see* Educational Effectiveness Theory and Research: Recent Advances). The limitations of using a single approach to describe educational effectiveness have also been identified. As a consequence, integrated multilevel models of educational effectiveness have been developed. Specifically, researchers attempted to integrate the findings of school effectiveness research, teacher effectiveness research, and the early input–output studies, and the models which emerged (e.g., Creemers, 1994; Scheerens, 1992; Stringfield and Slavin, 1992) have a multilevel structure, where schools are nested in contexts, classrooms are nested in schools, and students are nested in classrooms or teachers.

Fourth Phase: Analyzing in More Detail the Complex Nature of Educational Effectiveness

During the fourth phase, researchers attempted to respond to a major criticism of earlier EER that was concerned with the failure of the field to contribute significantly to the establishment of strong links between research on effective factors and developmental work so as to improve the quality of education. However, a dynamic perspective of education is now being taken into account more explicitly in theoretical and empirical EER studies (Creemers and Kyriakides, 2008). Thus, in this phase, teaching and learning are seen as dynamic processes that are constantly adapting to changing needs and opportunities. Thus, studies investigating the process of change in schools gradually emerged (Opdenakker and Van Damme, 2006). Implications of the findings of these studies for modeling educational effectiveness in a way that takes into account the complex nature of education (Creemers and Kyriakides, 2010) can be drawn. Moreover, such studies helped us look at the functioning of each effectiveness factor using a dynamic rather than an instrumental perspective. An example of such a theoretical model is presented in the article Theories of Educational Effectiveness namely the dynamic model of educational effectiveness (*see* Educational Effectiveness Theory and Research: Recent Advances). This also implies that specific developments in the methodology of EER are needed since this research does

not support the traditional approach of modeling effectiveness as a static feature or attribute of schools or teachers (Creemers et al., 2010). Modeling effectiveness or change should not be restricted into fitting conditional models in which measures of student learning outcomes (adjusted for background characteristics such as SES, gender, and prior knowledge) are regressed on a set of explanatory variables. Further, measures of change based on only one or two time points are also unreliable (Goldstein, 1997) and so provide an inadequate basis for studying change (Gustafsson, 2013). Therefore, the approach promoted in the current phase of EER does not give undue emphasis on measuring the short-term outcomes of the immediate effect of schools and teachers on student achievement gains during a single school year. In contrast, this approach instead reveals a need for longitudinal research to study results of schools and classrooms and their functioning over a longer period, modeling the growth in student outcomes over at least three time points.

Methodological Developments Promoting Theory and Research on Effectiveness

This section attempts to show that much of the progress of EER is due to advances in methodology made during the last 30 years. During the first phase of EER, major emphasis was given to conducting outlier studies and comparing the characteristics of more effective schools with those of less effective schools such as the Louisiana Study (Teddlie and Stringfield, 1993). However, the emphasis on identifying outliers was criticized for both conceptual and methodological reasons (Goldstein, 1997). During the 1980s, researchers moved to the use of mainly cohort and longitudinal designs involving larger numbers of schools and students and such studies multiplied in the 1990s. In addition, the development of hierarchical regression approaches that are involved in multilevel modeling techniques enabled researchers in the area to take the multilevel structure of educational systems into consideration and thereby deal with the methodological weaknesses of earlier studies which used only unilevel regression analysis (the 15 000 h study by Rutter et al. (1979)). Early examples of studies which made use of hierarchical regression approaches include the School Matters (Mortimore et al., 1988) and the Inner City Infant School research (Tizard et al., 1988) in England. Gradually, the way of measuring the links between inputs, outcomes, and processes became more sophisticated particularly through the development of contextual value-added models that controlled for student level prior attainment and background as well as contextual measures of school or class composition. Moreover, progress in the area of developing tests and other assessments helped researchers establish better measures of achievement not only in the area of basic skills such as reading, writing, and mathematics but also in higher-level cognitive outcomes and even in the affective and social domains.

During the second and third phases of EER, a large number of reviews were conducted and their main purpose was to provide the research community and policy makers with the latest developments from the field (Levine and Lezotte, 1990; Sammons et al., 1995). However, although these reviews were usually based on a collection of studies which were seen by the authors as providing good examples of research, their judgments of the methodological deficiency of studies that were excluded were not necessarily systematic and were often based on implicit rather than explicit criteria. On the other hand, the reviews which were not selective resulted in a huge number of factors for which not much information about their empirical support was provided (Levine and Lezotte, 1990). As a consequence, the results of these early reviews can be questioned. In this context, carrying out meta-analyses using advanced quantitative approaches can be seen as a major methodological development which promotes the theoretical development in the field and enables researchers to identify generic and more specific factors whose impact is dependent on the educational setting in which they are operating (Scheerens and Bosker, 1997).

During the third and fourth phases of EER, emphasis was given to searching for not only predictors with direct effects on student outcomes but also those with indirect effects. Moreover, the theoretical models that have been developed during this phase refer to relations among factors situated at different levels (Creemers and Kyriakides, 2008; Scheerens and Bosker, 1997). In this context, the development of multilevel structural equation modeling (SEM) approaches enables researchers to search for indirect effects and/or test the validity of the current models of EER in relation to this assumption.

During the fourth phase of EER, emphasis is given to modeling the dynamic nature of effectiveness. This implies, among other things, that longitudinal studies which last for at least 3 years should be conducted not only to measure the long-term effect of schools and teachers but also to find out how changes in the functioning of factors are associated with changes in educational effectiveness (Creemers and Kyriakides, 2010). For this reason, developments in advanced quantitative research methods such as the use of growth modeling techniques are to be welcomed because they can help us answer such research questions. Moreover, conducting longitudinal studies enables researchers to search for reciprocal relations which, according to current theoretical developments in the field of EER, are expected to exist. Such relations are often included in relevant statistical models and refer to the relation of student factors that are likely to change with achievement. For example, advanced SEM techniques can be used to search for reciprocal relations between motivation or academic self-concept and student achievement by making use of data collected at different points of time (Marsh et al., 2006).

At this point, we would like to claim that a challenge for EER is to make better use of current developments and progress in research methodology and to provide empirical support for new ways of conceptualizing the dynamic nature of educational effectiveness. At the same time, it is acknowledged that the knowledge base of educational effectiveness and its attempt to establish theoretical models challenge the development of methodologically appropriate studies and ways of analyzing data. An example is the development of SEM and multilevel techniques which help EER to search not only for linear but also for nonlinear relations between effectiveness factors and student achievement. Furthermore, a challenge for EER research methodology is to establish and use advanced quantitative techniques which will identify meaningful grouping of factors

(Kyriakides et al., 2009). Such a development will contribute to the establishment of stronger links between EER and those who are involved in school/teacher development or improvement projects that seek to promote better practice (defined as that which promotes better outcomes for students) and offers the hope that more comprehensive strategies for school improvement will eventually emerge (Creemers et al., 2013).

Improving Quality in Education: The Contribution of Educational Effectiveness

In the first parts of this article, it was made explicit that the main research question underlying most educational effectiveness studies is to identify factors at different levels (e.g., school, class/teacher) that are associated directly or indirectly with students' learning outcomes and to seek to explain (through reference to theory) why these factors influence students' learning outcomes. This implies that EER attempts to establish and test theories which explain why and how some schools and teachers are more effective than others in promoting better outcomes for their students. Thus, the first area of investigation for this field is concerned with the development and validation of the theoretical framework of educational effectiveness. By doing so, researchers attempt to establish and validate a knowledge base that can be used for improving educational practice and that is of relevance to both policy makers and practitioners.

The relevance of the knowledge base generated by researchers for use by policy makers and practitioners suggests that beyond modeling effective practices, a second area of investigation that needs to be examined is the use of this knowledge base for improvement purposes. The importance of this second area of investigation reflects the fact that the ultimate aim of EER is to improve practice and it argued that improvement is most likely to be achieved by helping schools and teachers make use of the research-generated knowledge base of EER in order to develop their improvement strategies and actions (Scheerens, 2013). In this article, we move a step forward and suggest that the research agenda of the current phase of educational effectiveness may be expanded not only by attempting to develop a valid theoretical framework but also by investigating under which conditions this framework can be used for improvement purposes. This argument is based on the fact that experimental studies are mainly conducted by researchers in this field in the USA. These studies not only help us to demonstrate cause and effect relations in a more systematic way but also to design interventions that are concerned with the improvement of factors associated with student achievement. Moreover, an attempt to make use of theories in designing school improvement interventions can be identified in several European projects (see Creemers and Kyriakides, 2012).

In this context, the dynamic model of educational effectiveness was used in developing an approach for teacher and school improvement purposes. The proposed dynamic approach promotes the design of improvement projects that are based on a theory which has been systematically tested. This approach is described in the article on school improvement (*see* School Effectiveness Research). This implies that relying only on school stakeholders' experiences can be limiting in terms of their school development and improvement, since there appears to be little, if any, evidence from the published literature that assisting the school stakeholders to engage in any developmental or improvement program without providing them with a validated framework to meet their personal needs and identify priorities for improvement necessarily improves their effectiveness. Although each school is treated as a professional community responsible for designing and implementing its own improvement strategies and action plans, school stakeholders are not left alone to design and implement their strategies and actions, but are encouraged to make use of a research and advisory team to design their action plans. Therefore, a systematic research-based approach to design, implement, and evaluate improvement efforts is promoted by the dynamic approach (Creemers and Kyriakides, 2012). More specifically, school stakeholders are expected to collaborate with the research and advisory team and develop evaluation mechanisms in order to identify priorities for improvement. During the implementation of the interventions, formative evaluation mechanisms are also established in order to help schools take decisions on how to improve their improvement strategies and action plans. A number of experimental studies demonstrated the added value of the dynamic approach for school and teacher improvement purposes (Antoniou and Kyriakides, 2011; Demetriou and Kyriakides, 2012). This implies that educational effectiveness can contribute not only to the development of theories explaining the complexity of education but also to the establishment of intervention programs that are based on a theory-driven and evidence-based approach.

The review of EER presented in this article seems to show that educational effectiveness remains a dynamic field of enquiry and, if no longer in its adolescence, is still certainly in an early stage of maturity. Educational effectiveness remains an exciting area with many possibilities to influence not only policy and practice but also the development of advanced methodological approaches to study education. There are numerous opportunities to consolidate, refine, and extend the existing knowledge base of school and teacher effectiveness and, in particular, to develop its methodology further. Moreover, the need for better links with (and contribution to) thoughtful school improvement and evaluation studies remains urgent.

This article is a revision of the previous edition article by H. Wottawa, D. Pult, volume 6, pp. 4255–4259, © 2001, Elsevier Ltd.

Abstract

Evaluation of educational programs requires evidence of both efficacy, typically from randomized controlled trials, and effectiveness of program implementation. In order to provide useful evidence to support policy, program evaluations must demonstrate that the program can work under optimal controlled conditions and that it will work when rolled out on a large scale in community settings. Evaluation benefits from a combined methods strategic plan to address these different aspects of effectiveness.

Educational Evaluation

Educational evaluation addresses the effectiveness of program interventions. Within education these typically concern learning, e.g., reading; behavioral, emotional, and social development, e.g., antibullying programs; or broader topics, e.g., whole school system changes such as inclusive education. Debates have raged within the research community about methodology, in particular the place of qualitative methods in the evaluation of program effectiveness compared with quantitative methods. There has also been strong political involvement with some governments taking positions on the type of evidence required for evaluation studies, in particular the emphasis on randomized controlled trials (RCTs).

The first aim of program evaluation is to discover whether the intervention is effective. This may be small scale, e.g., a school investigating the introduction of a new reading scheme, but evaluation can also be large scale, at school, district, state (local authority (LA)), or national level. The availability of national or state data sets such as the U.K. Government's National Pupil Database and its student-level School Census provides opportunities for large-scale evaluations of educational interventions, including curricular reforms (e.g., Bhatt and Koedel, 2012) or the differential development of groups of students (e.g., the relationship between identification of special educational needs and ethnicity: Strand and Lindsay, 2009). Increasingly, however, the importance is being recognized of the need to evaluate both the effectiveness of the program itself and its implementation.

Methods

In the past there was a strong commitment to experimental methods for evaluation research. The favored 'gold standard' method was the RCT, a design whereby participants are allocated randomly to an intervention or nonintervention group. Comparison of results indicates the relative effectiveness of the program compared with either no intervention (or 'provision as usual') or an alternative intervention, such as an existing program. This approach continues to be regarded as the most effective method for examining causal relationships, i.e., whether improvement is as a result of the program, but see Shadish et al. (2001) for a comprehensive review of methods.

The use of RCTs is increasingly recognized as necessary but not sufficient. Ultimately, a program demonstrated to be highly effective by RCTs will only be useful if its implementation in 'real life' is also effective. RCTs are typically small scale in order to maximize their rigor, which is facilitated by very strong control being exercised by the researchers. This includes high levels of specificity of both independent and dependent variables, and strong adherence to the required protocols for implementation, including number and length of sessions, who may administer the program, training requirements, and data collection. The evaluation of education programs will typically need to address complex issues. For example, schools differ in type, staff interest in the research, their levels of relevant competence and motivation. This may be at the level of the program itself or scale of implementation. For example, a program to develop reading may focus on a particular element such as letter sound-symbol or whole word learning; the development of reading, however, requires both skills and is influenced by many other factors. Rigorously controlling implementation of a program may be possible in a small-scale trial but impractical across a large number of schools. Consequently, fidelity to the program may vary: schools may change key elements of implementation, and to different degrees.

Other methods contribute to improve the evaluation of implementations. Meta-analyses enable the weight of evidence across studies to be examined: consistency of strong effects indicates support for the program's effectiveness and generalizability. However, meta-analyses typically indicate a range of effects across studies which raise the question, why do results vary? A third approach, therefore, is to examine the reasons not only for the effectiveness of a program, but also its variability and even its noneffectiveness. Qualitative methods are appropriate for this, including interviews with key participants to explore in depth what was successful about the program (perhaps not all elements were effective or necessary), for whom (variations across different participants) and, primarily, the reasons for different levels of effectiveness for different participants.

Increasingly, evaluations are designed as combined (or mixed) methods studies. Here, research methods are combined to address different research questions within the overall

examination of effectiveness, drawing on the strengths of different approaches. A number of combined methods designs are possible taking into account the relative proportion of quantitative and qualitative methods, the number and the arrangement of stages – concurrent or sequential – and, if the latter, the nature of the sequence (Leech and Onwuegbuzie, 2009). See also Tashakkori and Teddlie (2010) for a comprehensive overview.

Context

Both the micro and macro contexts of a program implementation are important. Introducing and running a program in a school will be assisted or hindered by the institution's view of the program itself, the priority of the topic in the school's development planning, and school leaders' views of supporting research given other priorities. Macro-level issues include the professional debates about a particular program and different methodologies; the political views on the importance and priority of the program domain; and the nature of evaluation. For example, recently in both the United States and England there has been a strong government commitment to evidence-based (or evidence-informed) practice, although the implications of that commitment have varied. Politics, national and local, may have an impact on evaluation in terms of technical/methodological positions, for example, the nature of appropriate evidence; or through broader values and the social policies that follow from these, and hence particular areas of intervention, particularly where funding is controlled or influenced politically.

Intervention and Implementation

There is increasing recognition that evaluation must address both the program and its implementation. Both technical/methodological factors and values, at the levels of both social policy and methodological approaches, are also important. For example, there is now appreciation of the importance and benefits of engaging research participants in the research enterprise, not simply as passive providers of data (Lewis and Lindsay, 2000): Enabling participants' voices to be heard may take many forms including research design, gathering their perspectives as data, and their involvement in dissemination (Roulstone and Lindsay, 2012).

Evidence for the effectiveness of programs has increased in education and other fields. Web-based resources provide researchers and practitioners with access to evidence for the effectiveness of interventions for learning (e.g., What Works Clearing House: http://www.ies.ed.gov/ncee/wwc/), parenting programs (United Nations Office on Drugs and Crime: http://unodc.org/), and the recent What Works for SLCN? (Speech, Language and Communication Needs: https://www.thecommunicationtrust.org.uk/whatworks). These resources are also available to the public. Hence a parent may check the evidence on an intervention proposed for their child.

The research base for evaluating implementation is less well developed than RCTs for efficacy trials (Fixsen et al., 2005) but is growing. Meyers et al. (2012) have produced a conceptual overview and proposed a Quality Implementation Framework of four phases comprising 14 critical steps:

- Initial considerations concerning the host settings.
- Creating a structure for implementation.
- Ongoing structure once implementation begins.
- Improving future applications.

Evidence: From Efficacy to Effectiveness

Educational evaluations may comprise particular research studies of an individual program. However, in order to develop evidence-based practice the evaluation enterprise must have a broader conceptualization, demonstrating that:

- Interventions are effective.
- A policy for implementation has been approved, at a local, regional, or national level.
- Systems are available for ensuring that teachers or other relevant practitioners and policy makers concerned with implementation have the required knowledge and skills to interpret the evidence.
- Practitioners and policy makers have the knowledge and skills to implement the program with fidelity.
- The context in which to host the implementation is supportive.
- There is understanding of the likely cost effectiveness and cost benefits of the program.
- There is the will to support the program with appropriate leadership and resources.

In support of achieving this comprehensive approach, a staged approach is necessary:

- The program must be derived from sound theoretical analysis for which there is also an evidence base.
- A program must be developed which operationalizes the theoretical underpinnings such that it reflects the relevant principles derived from this analysis.
- The program requires an evidence base for its content and its implementation including target population; amount, frequency, and intensity of implementation ('dosage').
- Initial trials of the program to test out the content and practical elements.
- An efficacy trial that meets quality standards, typically an RCT (Society for Prevention Research: http://www.preventionresearch.org/) and demonstrates positive effects.
- Further efficacy trials with positive results to demonstrate generalizability.
- Efficacy trials that demonstrate sustainability of the program, with effects maintained over time.
- Effectiveness studies to examine whether the program continues to show effectiveness when it is implemented on a large scale in community settings.

This approach to evaluation must be fleshed out taking into account the issues addressed above, including the use of combined methods, ensuring the voice of key participants is accessed and reported, and the importance of both practical and political in addition to technical factors. Generalization of findings to other populations must also be examined, not

assumed, including variants by ethnicity, socioeconomic disadvantage, and intellectual status (Hastings, 2013).

Example

The Parenting Early Intervention Programme (PEIP) was implemented by the U.K. Government (2006–11), initially in 18 LAs (school districts). It was one response to concerns about antisocial behavior of children and young people (Respect Task Force, 2006). A commissioned review identified parenting programs shown to be effective, typically by RCTs (Moran et al., 2004). An effectiveness study in community settings in 18 LAs (over 2000 parents: 2006–08) demonstrated that after attending one of the three programs used in the PEIP parents had lower levels of less-effective parenting skills (laxness and overreactivity) and improved mental well-being, with borderline large effect sizes (Lindsay et al., 2011a). The parents also reported their children having lower levels of behavior problems (with borderline small to moderate effect sizes).

Interviews with parents, group facilitators, and LA staff were used to identify the factors that supported or hindered successful implementation across the LAs (Lindsay et al., 2008). On the basis of the evaluation data, the Government funded a national rollout to all English LAs (2008–11). This too was evaluated (over 6000 parents) and demonstrated similarly positive effectiveness. A 1-year follow-up of over 1000 parents indicated that the improvements in parenting skills and children's behavior were largely maintained (Lindsay and Strand, 2013). The qualitative strand provided supportive evidence for the main factors for successful implementation including strong leadership, effective day to day management and organization, and a clear policy for parenting support (Lindsay et al., 2011b). Together, the evidence from quantitative and qualitative methods in this large-scale combined methods evaluation influenced national policy.

Conclusion

Implementation evaluation is a key element in determining the effectiveness of an intervention: RCTs may provide evidence of efficacy of the program, often under particularly favorable conditions, but for the development of evidence-based policy and rollout of programs on a large scale, it is essential also to evaluate the factors that increase the likelihood of success and reduce the possible adverse impact of factors likely to impair effectiveness. An evaluation strategy is needed which collects evidence on program efficacy, and on effectiveness when implemented on a large scale, and with a range of populations, allowing the development of a strong evidence base to support policy and practice.

Abstract

Treatment of the topic in this article is restricted to institutions of general higher, secondary, and elementary education. It is important, however, to be aware that a clear distinction between these levels was not established before the eighteenth century. In the introductory section of the article a distinction between nonformal and formal educational institutions is proposed to characterize educational practice during the classical Greek period, compared with the schools established much earlier in the Sumerian city states or those later founded in the towns bordering the Mediterranean and Aegean Seas during the Hellenistic period. The liberal arts curriculum evolving in these latter schools had a strong impact on the course of studies in the cathedral schools and in the liberal arts faculties of the universities up to the early modern era. This is illustrated for the Middle Ages, focusing on the development of schools and of institutions of higher learning in France and somewhat later in Central Europe (Sect. 2). Section 3 examines the impact of the humanistic movement and of the Reformation on developments in the field of education. Changes in curricular contents and objectives are noted in the teaching of classical literature and languages. The role of the state in the control of educational institutions is considerably strengthened, although their relation to the church remains a close one. In the Protestant regions of northern and Central Europe a spurt in the spreading of literacy is to be observed, but even there, obligatory schooling was fully enforced only in the second half of the nineteenth century. Whereas, in France, universities and colleges of the Ancien Régime were suppressed by imperial order in 1793 and, in their stead professional schools were organized, universities in Central Europe consolidated their dominant position in higher education and succeeded in safeguarding a sphere of autonomous decision making: Section 4 recounts the evolution of the modern university between 1694 (foundation of the University of Halle), 1734 (foundation of the University of Göttingen), and 1810 (foundation of the University of Berlin), a process characterized by, for example, the substitution of Latin by the vernacular as medium of instruction, the introduction of new fields of knowledge, an increasing emphasis on research relative to teaching increasing specialization in both teaching and research, with the consequence of the emergence of new disciplines. These developments affect the role of both teachers and students. Throughout the nineteenth century, remarkable changes are discernible also at the level of elementary education (rising enrolment rates, creation of institutes for the education of elementary teachers) and secondary schools (establishment of different types of secondary schools varying in curricular emphasis, rising enrollment rates for female students, although parity was not achieved until the second half of the twentieth century, expansion of regional and central bureaucracies for both elementary and secondary schools (see Sects. 5 and 6 for parallel developments in England France and Germany)). At the turn of the twentieth century coherent systems of education had emerged in the more developed European nations, representing what has more recently been termed a 'global model of schooling.' The thesis that we have been witnessing the 'formation of a world educational system' is discussed in the final section, with reference to the activity of international agencies in educational policy and to the situation in developing countries.

Origins

Any attempt to specify a starting point for the history of educational institutions is necessarily arbitrary. This is due to the uneven and contingent distribution of early historical sources across time and space, as well as to the fuzziness of the term 'educational institutions.' Broadly speaking, the term refers to a set of rules that govern the aims and activities of the adult generation in socializing the young generation into more or less age-graded roles. Knowledge about how to profit from the extended period of human infancy in order to further physical and moral cognitive development must have been part of the everyday wisdom of the older generation long before precepts concerning education appeared in religious texts. And even after the introduction of educational institutions in a more narrow sense of the term (schools), these rule-sets governing everyday socializing educational practice remained of prime importance as these formal institutions were highly specialized and, for centuries to come, reached only a small minority of a population.

The boundaries between religious or general cultural practice and educational practice and the respective institutions in these fields are not clearly marked. Thus, for ancient Jewish education the basic set of texts is identical with the literature guiding religious practice: the Pentateuch, the oldest part of the Old Testament, i.e., the books Moses 1–5. Of course, those parts of the text referring directly to education are clearly recognizable as such but, obviously, their interpretation (e.g., in the Talmud) depends on the religious context and vice versa (Schwenk, 1996, pp. 153–177).

For example, we are most familiar with an educational practice that is not primarily channeled through educational institutions in the narrow sense of the term but rather builds on participation in cultural, social, and political activities in a highly dynamic society, namely that prevailing in ancient Greece during the classical period (for the following, see Marrou, 1948; Schwenk, 1996). This does not hold, of course, for Sparta, where the male child left the family at the age of 7 years to join a state-controlled educational system for the next 12 years bent on producing fearless and obedient warriors.

Athens at that time had not developed a public system of schools; military training of 2 years' duration was introduced only in the late fourth century BC. Education of the young (boys) was the responsibility of the family, which availed itself of the services of private teachers. Boys of fathers having full citizenship had the right, at age 10 years, to be present at most cultural events. Although the works of the poets and historians were available in writing and many of the (male) citizens must have been literate to be able to fulfill their public duties, Greek culture of the classical period was to a large degree an oral culture. Festivals, the theater, and competitions in presentations of dance, music, poetry, drama, and athletics provided ample opportunity to familiarize the young generation with the rich heritage of Greek civilization. This experience was understood to be more than a means to achieve esthetic refinement; it exposed the young to reflections on human destiny and justice, concepts of virtue and models of conduct and of good governance. It was preparation for citizenship and moral education. Physical education and music education, too, were considered fundamental for the formation of the free citizen. Especially the former was seen as part of the preparation for military service, and the communes were responsible for providing and controlling localities for athletic activities. The growing prestige of the Panhellenic games may, however, have served to weaken the nexus with military training.

Many elements of the (nonformal) curriculum of the classical period reappeared in the curriculum of the public schools provided by the larger communes during the Hellenistic era, normally dated from 338 BC when Philipp II of Macedonia defeated Athens and their confederates in the battle of Chaironeia. In both periods the curriculum was strictly oriented toward general as opposed to vocational education. The adult role emulated in the schools is not that of the skilled professional but that of the citizen potentially responsible for different general tasks in and for his community and in need of general moral as well as cognitive competences.

Educational institutions of a more restricted vocational orientation had already been introduced long before the apex of Greek civilization in the Sumerian city states of the third millennium BC. These were highly differentiated societies facing complex administrative challenges and had important trading relations. To document and control their diverse activities they needed systems of book-keeping for the different administrative fields and functions. Considering the state of development of the sign system for writing, mastering this task required systematic learning. Consequently, writing schools for trainees of the administration were established (Feldbusch, 1988, pp. 1473ff). Comparable institutions specializing in the education of scribes, administrators, and probably also artisans had already existed in ancient Egypt (Craig, 1981; Adick, 1992, pp. 164ff).

The Hellenistic system of postelementary education which prospered not only in the Greek communes but also in many regions bordering on the Aegean and Mediterranean Seas, and which functioned in the eastern part of the empire until the fall of Byzantium in1453, is important for further developments during the Middle Ages in Europe in several respects: it provides the context in which early Christian concepts of education were developed in close contact with classical pre-Christian educational theory. The curriculum of the Enkyklios Paideia Septem Artes liberales remains a point of reference in the debate on the contents and objectives of postelementary education, even gaining in importance with the growth of first-hand knowledge of the classical texts in central and Western Europe.

The Middle Ages

The cathedral schools first founded toward the end of the eighth century and spreading throughout the Carolingian Renaissance provide evidence of this type of long-term curricular continuity (Verger, 1986). Although their primary purpose was the education of the clergy via an in-depth study of the Holy Scripture, they also introduced their students to a version of the trivium grammar, rhetoric and – around the end of the tenth century – dialectic. Thus, these schools offered a relatively broad general education, including the study of classical nonreligious texts, as a basis for the professional preparation for the clergy. Some of these schools developed into universities in the first half of the thirteenth century, the largest and, with respect to the quality of its liberal arts and theological faculty, perhaps the most important among them the University of Paris, which attracted large numbers of students from England, the German-speaking regions of Europe and Italy. Among its famous teachers were Albertus Magnus (1240–48), Bonaventura (1248–57), and Thomas of Aquino (1252–58 and 1268–72) (Verger, 1986, p. 421). Their names, like Duns Scotus, Roger Bacon, and Occam, also point to the importance of the Christian orders, foremost among them Dominicans and Franciscans, as centers of the rich intellectual life and scholarly learning of the twelfth and thirteenth centuries. The attractiveness of the University of Paris was comparable to that of law schools in northern Italy (e.g., Bologna and Pavia), which served as models for the rest of Europe. The hierarchical relation between professional schools of theology, law (Orleans), or medicine (Montpelier) at the top and the ancillary and preparatory functions of the liberal arts faculty, typical of the university up to the end of the eighteenth century, is already discernible in some of the French cathedral schools of the eleventh and twelfth centuries. This may have helped to preserve the idea that higher education should be more than just a rather restricted professional training. When, by the late Middle Ages, much of the knowledge acquired in classical antiquity and preserved in the centers of learning of the eastern part of the Roman Empire had been recovered, this offered the opportunity to widen the scope of scholarly learning to approximate the full range of the classical liberal arts curriculum by including parts of the quadrivium: arithmetic, geometry, music, and astronomy. To be sure, this was already the vision of Alcuin – teacher and close counselor of Charlemagne, learned author of textbooks on the seven liberal arts and very active in the propagation of cathedral schools in the early ninth century. In most of the French cathedral schools, however, teaching of the liberal arts seems to have been restricted to the trivium.

When the first German universities were founded in the second half of the fourteenth century (beginning with Prague in 1348), they followed the organizational pattern developed in the older European universities: the liberal arts faculty was

by far the largest but ranked lowest. The faculties of theology and law enjoyed the highest prestige and the best remuneration of their teachers. In most of these universities, however, the arts faculties covered the full range of the arts, including natural science on the basis of Aristotle's writings (Paulsen, 1919, Vol. I; Ruegg, 1993, 1996, Vol. 1).

The larger and more successful European universities were international in the composition of their student bodies and teaching faculties, which, of course, was rendered possible by the use of Latin as the lingua franca of higher learning. Students were attracted by famous teachers and these, too, traveled much in search of better conditions for their work. Thus, knowledge spread fairly quickly, but was accessible only to that small minority who mastered the medium of communication. Schools that could have transmitted the necessary skills were small and widely dispersed. Demand for this type of instruction was low for a host of reasons. Until the end of the eighteenth century there was no clear demarcation between the respective functions and objectives of schools and universities.

By the end of the fourteenth century, most European towns of some importance had one or more schools. They were attached either to a parish, a convent, or a chapter, or directly sponsored and controlled by the communes. The latter form, with the supervision of the town's council, seems to have prevailed in Germany. But here, too, the relation between school and church remained a tight one. In many cases the minister of the church was himself the teacher or he may have acted as rector of the school, responsible for the selection of a teacher who, in turn, chose his own teaching assistants. The pupils were taught in two or more groups formed on the basis of age and learning progress. The main objective of the town school was to teach the pupils to read and to write Latin. It seems remarkable that these schools took in not only the children of well to-do families but sometimes also a sizable proportion of poor children living on charity (Paulsen, 1919, Vol. I, 18ff).

The Humanistic Movement and the Reformation

Around the turn of the sixteenth century, universities and schools were shaken by two interdependent events: the humanistic movement, originating in the Italian Renaissance, and the Reformation (Ruegg, 1993, 1996, Vol. 2). The humanistic movement was a polemic revolt against the culture and learning of the Middle Ages, which it condemned as a dark, narrow, uninspired, mechanistic, unnatural, and bookish educational tyranny; and it was a movement for a fresh reading of the poets and philosophers of classical antiquity in their original language – Greek, Latin, Hebrew – a re-reading freed from the pressure to prove this literature's compatibility with Christian values and dogma. It was, last but not least, a plea for a study of (human) nature, unfettered by the authority of classical literature (for a contrasting evaluation, compare Paulsen, 1919, Vol. I, Chapters 3–5; Garin, 1964, pp. 25ff).

The movement's immediate effect on the schools seems to have been rather limited, depending on the conditions encountered locally: the prestige of the classical languages was raised, new textbooks written or recommended by devotees of the movement were introduced, some schools hired a poet to teach the basics of Latin poetry and eloquentia. In a small number of schools, Greek was introduced as a new subject. The long-term effects, on the other hand, were important to both schools and universities: The curriculum of the liberal arts faculty was considerably extended to include Greek language and literature which was, like Latin literature, to be represented in a fairly wide selection of poetry philosophical, historical, mathematical, and other scientific texts. Most arts faculties also offered courses in Hebrew. This increase in service functions opened teaching positions for humanists and doubtless raised the prestige of the arts faculties. In the larger schools created in the course of the sixteenth century by combining several smaller Latin schools, too, Greek was offered as a new subject; in some of them even an introductory course of Hebrew was taught. Several of these larger academic schools in fact covered areas of knowledge that were traditionally part of the curriculum of higher education.

As for the effects of the Reformation on the development of educational systems, only two aspects will be mentioned here: it supported the relatively fast spreading of literacy in the mainly Protestant areas of northern Europe (the concept of universal priesthood combined with the accessibility of the sources of faith translated into the vernacular to every literate person). Sweden seems to have been most successful in this respect. Already in the seventeenth century, admission to full church membership was tied to the ability to read. Prussia was the first state to initiate steps toward compulsory elementary education early in the eighteenth century. Other Protestant states followed suit early in the nineteenth century. Fairly reliable quantitative data on the development of attendance at primary schools and on the spreading of literacy are available only for the decades from about 1830 onwards. In both respects, they show a considerable advantage for the Protestant territories (Flora, 1975; Flora et al., 1983).

In central Europe, in particular, the Reformation changed the relation between the university and the polity. The universities became part of a territorial state with a distinctly denominational character that assumed control over the reorganization of the religious system and of the educational institutions still closely connected with it. This process entailed a loss of autonomy on the part of the universities, a loss which increased with the growth of the central state administration This is clearly visible in the Protestant territories, where the ruling dukes and princes were actively engaged in the process of reorganizing the universities and of creating a new type of academic school (Landesschule, Furstenschule), financed directly by the state and recruiting its students more or less statewide. The control of the elementary schools, financed by the communes with few additional resources provided by the state, remained mostly in the hands of the church. Towns continued to be responsible for the establishment and financing, mostly via fees, of Latin schools or different types of intermediate schools without foreign language instruction for children of well-to-do families (Leschinsky and Roeder, 1976). To remit (partly) fees for motivated pupils from poor families seems to have been widely practiced.

In England, the impact of the Reformation on school development might have been even stronger than in central Europe: "modernization of the educational system dates from

the Reformation. It was during this period – from the early mid-sixteenth to the mid seventeenth century – that grammar schools were established in most market towns, with separate school buildings being erected and teaching being developed as a profession, and a systematic approach to the structuring of the content of education … took root" (Muller et al., 1987, p. 93).

Despite the changes observable in the schools and universities during the sixteenth century, they still had more in common with their precursors of the late Middle Ages than with the modern system of education which slowly evolved at the end of the eighteenth century and which developed with increasing rates of change and growth from the middle of the nineteenth century onwards. The main function of the university still is the transmission of a cultural tradition legitimized by traditions. Where such traditions were not established as in the case of Protestant theology, this led to bitter and fruitless quarrels between adherents of dissenting factions of Protestantism, who had their strongholds in different universities.

There seems to have been little room for creative minds in the fields of philosophy, mathematics, and natural science. Descartes, Spinoza, Newton, and Leibnitz stayed out of its bounds. Hopes for the progress of knowledge and for innovations with the potential of improving the lot of mankind concentrated not on the university but on the Academy, an association of men of proven ability, especially in mathematics, science, and technology (Stichweh, 1984, pp. 67ff). That the academies established in Germany did not pose a threat to the position of the universities is mainly due to the fact that the latter, from the start of the eighteenth century, had embarked on the road to an ambitious reform.

Reforming the University

The University of Halle, founded in 1694, acted as forerunner and model in this development. It succeeded in attracting a number of outstanding teachers, among them August Hermann Francke, one of the heads of the Pietistic movement and an original pedagogical thinker, Christian Thomasius, a jurist influenced by Grotius and Pufendorf, who also taught and published in the German language, Christian Wolf, mathematician and an eminent advocate of rationalistic philosophy, who also published textbooks in German, and J.S. Semler, a theologist (1752–91) who was among the first to introduce the historical–critical method into the study of the Holy Scripture. The curriculum of the faculty of philosophy was extended to include history, geography, mathematics, and the natural sciences; the law school offered lectures on, among others politics and natural law. Halle clearly pointed the way to a modern university that was no longer just a teaching institution but had begun to accept systematic research as a major function and service to society.

The second model university of the eighteenth century was that at Gottingen, founded in 1734. Its focus was on the modern disciplines: political sciences, history, law, mathematics, and natural sciences; however, it was equally important for the development of the study of the civilizations and literature of classical antiquity. Lectures were given regularly in German. There existed something like a common understanding that it was an obligation of the university to extend knowledge in the respective disciplines by doing original research. Like A.H. Francke in Halle, both Gesner and Heyne, the dominant figures in the field of classical studies in Gottingen, were influential in improving the preparation of teachers and the educational practice in schools.

Whereas in France the universities and colleges of the Ancien Régime were suppressed by imperial order in 1793 and, in their stead, a series of professional schools were organized (Verger, 1986), universities in Germany consolidated their dominant position in higher education and succeeded in safeguarding a sphere of autonomous decision making in the organization of their teaching and research. The pattern of the further development throughout the nineteenth century and beyond was already clearly discernible in the conceptual framework elaborated by Fichte, Schleiermacher, and W.v. Humboldt for the foundation of the Berlin university in 1810: the traditional ranking of the faculties was to be abolished; a central role was ascribed to philosophy, in the sense that a philosophical spirit ought to pervade work in all fields of study. The mission of the university was defined as science in the service of truth, i.e., doing research to extend the boundaries of knowledge. This mission explicitly included the students. They were expected, fairly early in the course of their studies, to choose topics of interest where they could do original work on a restricted scale, the results of which were to be presented and discussed in the seminar. The seminar provided a new setting for teaching and learning, adapted to the new mission of the university: a regular meeting of a professor with his more advanced students for the purpose of discussing original research presented either by the professor or by a student.

A growing specialization of both teachers and students and the formation of subdisciplines was one important effect of these developments, regarded as ambivalent by those concerned with the preparation of teachers for academic secondary schools, that profession to which most students of the philosophical faculty aspired (Paulsen, 1919, Vol. II, pp. 259–278). For a comparative perspective on the "transformation of higher learning … expansion, diversification, social opening, and professionalization in England, Germany, Russia and the United States" see Jarausch (1982).

Schooling in the Eighteenth and Nineteenth Centuries

The first decades of the nineteenth century were not only a period of change for the universities. They also saw the evolution of the dominant type of academic secondary schools (Gymnasium), the curriculum of which centered on the classical languages Latin and Greek and, to a lesser degree, on mathematics and German, without completely neglecting the study of history, geography, and science. Relations between secondary schools and universities were clearly articulated with the introduction of the final examination (Abitur) and the examination of teachers qualifying for employment (Muller and Zymek, 1987). Parallel developments were observable in France with the evolution of the Lycee and the introduction of the Baccalaureat in 1820.

With respect to the development of elementary education, wide regional variations in the actual enrollment of that age group for which compulsory education was mandated are observable in the first half of the nineteenth century. The highest proportion of enrollment around 1820 was reached in Saxony, totaling more than 80%. An average for the whole of Prussia in 1816 was (probably over) estimated at 60%. Three decades later, the least developed province of Prussia topped this mark with 70% of the age group under compulsory schooling actually enrolled. Obviously, there must have been a rather steady growth of the provision of elementary education over the period (Leschinsky and Roeder, 1976, pp. 137ff). The expansion of the provisions for teacher training seems even more remarkable: 17 new seminars for the education of elementary school teachers were established during the period, raising the total number to 38. Their yearly output of qualified teachers seems to have been sufficient to meet the growing demand.

In England, compulsory attendance was not introduced until the final decades of the nineteenth century. But there, too, a rapid increase in literacy throughout the century is to be observed, much of it due to the willingness of working class parents to pay for the education of their children in one of the many local private schools, which they often preferred to the cheaper schools established by the churches or by associations crusading for the education of the lower classes, as Thomas W. Laqueur contends (Stone, 1976, pp. 192ff).

The Emergence of Educational Systems

At the start of the twentieth century, coherent systems of education emerged in the more developed European nations. The elementary schools no longer stood apart from the rest of the system, but developed their function as feeder institutions for the secondary schools. Within the secondary system or between secondary and primary schools, new types of schools were established, varying in curricular focus prestige and entitlements conferred upon them. Well into the twentieth century, the classical academic secondary school with its clear focus on Latin and Greek languages and literature – lycees, colleges in France, grammar schools and, of course, the small number of highly prestigious boarding schools, the so-called 'Public Schools,' in England, and the Gymnasium in Germany – succeeded in defending its top position. Below this type ranked secondary schools that did not offer Greek or neither Latin nor Greek but, instead, taught modern languages and reserved more hours of instruction for the sciences: enseignement special in France, higher-grade schools in England, Realschulen, Oberrealschulen, Realgymnasien in Germany. Many of these schools emerged owing to the activities of local pressure groups convinced that the classical curriculum did not meet the educational needs of their children. The ambitious blueprints for their modernized curricula, integrating elements of vocational and of general education, however, had already been proposed from the second half of the seventeenth century onwards (Leschinsky and Roeder, 1976, pp. 168–208). Some of these types of secondary schools eventually achieved parity with the classical academic secondary schools – if not in prestige, at least in entitlements to matriculation (Prost, 1969; Muller et al., 1987; Muller and Zymek, 1987). Central and regional bureaucracies, responsible for the development and functional control of the system, were expanded early in the nineteenth century in France and Germany. This happened considerably later in England, where an effective substitute had been developed in the form of the Royal Commissions "with the brief of examining and making recommendations for the reform of all levels of education" (Muller et al., 1987, p. 88). Curricular frameworks and standards of examinations for different types of schools and teacher training were specified by the central administration, traditionally leaving most leeway for curricular decisions on the level of the individual school in England. The inclusion of females had progressed considerably throughout the nineteenth century, although parity was not achieved until the second half of the twentieth century.

A Global Model of Schooling

In reviewing the long-term evolution of educational institutions in the more developed countries of western, northern, and central Europe and in the USA, one gains the impression that, despite national peculiarities and the weight of regional traditions, the systems emerging at the turn of the twentieth century are basically similar in structure and functioning. They seem to represent what has more recently been termed a 'global model of schooling.' The thesis that we are witnessing the "formation of a world educational system" (Adick, 1995) implies that the dynamics fueling the development of systems of mass education presupposes the existence of the modern nation state and the concept of citizenship but that it is to an important degree transnational. This thesis has received substantial support in empirical research conducted by John W. Meyer, one of its principle proponents, and his collaborators (Meyer et al., 1992). Thus, an analysis of constitutions enacted since about 1870 shows that practically all of them include statements concerning the individual right of access to education and the authority and obligation of the state to provide and regulate the educational institutions (Boli-Bennet in Meyer and Hannan, 1979). The Prussian constitution of 1794 (Allgemeines Landrecht) can, at least in some respects, be cited as an important early precursor of these later developments. A study of primary school curricula enacted between 1920 and 1986 also reveals a high degree of communality with respect to, e.g., the subjects taught, hours of instruction per subject, and basic changes in the content of subjects across a large sample of countries (Meyer et al., 1992). Further support comes from case studies of educational developments in colonial and postcolonial West Africa (Adick, 1992, 1995) that document autochthonous initiatives in the course of the nineteenth and early twentieth centuries to establish a school system for the native population. The problem of whether the curriculum should cultivate native African traditions or emulate the best international models was, and still is, openly debated (see Reichmuth (1995) for the influence of Christian and Muslim communities on education in Nigeria and Wiegelmann (1999) for the development of schooling in Francophone Senegal, with special attention to the problem of the language of instruction, afflicting many of these countries).

More recently, the evolution of a global model of schooling has been actively promoted by international agencies: the Organization for Economic Cooperation and Development (OECD)'s 'Reviews of National Policies for Education' are

based upon a continuously refined set of common criteria and standards used in the evaluation of national educational systems. The European Union, too, may induce a further rapprochement between educational systems of member states; mutual recognition of qualifications certified in schools and universities can be viewed as a step in this direction. Large international quantitative studies of school achievement presuppose communalities in the curricula of primary and secondary schools, their success in constructing achievement tests, developed in international groups of researchers and valid in countries otherwise different, offers proof that such communalities exist in fact; and decisions of national educational administrations taken in reaction to test results may again push the trend toward globalization. This trend has recently accelerated, encouraged by developments such as the McKinsey report "How the world's best school systems keep getting better" (Mourshed et al., 2010), which purports to draw broadly generalizable conclusions from international studies, which would allow education systems to develop to international standards of excellence (Mourshed et al., 2010).

To be sure, the global model still leaves room for variation between countries, e.g., with respect to ensuring elite education for minorities of high achievers, in the degree of comprehensiveness of higher secondary education, in the organization of different types and levels of vocational and higher education, and in the importance assigned to specific subjects like, for example, religion.

A final remark addresses the problem of large gaps in the global model: both the quality and the inclusiveness of educational provisions are far below accepted international standards even on the level of primary education in a number of developing countries, despite considerable progress achieved in the decades between 1960 and 1980. The report prepared for the 1990 'World Conference on Education for All' presents a long list of deficiencies in, e.g., equity of access, completion of primary cycle preparation of teachers, quality of instruction, availability and quality of instructional materials, and managerial competences of personnel at the central, regional, and school level (Lockheed and Verspoor, 1990). The recommendations, elaborated in the report, for action to overcome these deficiencies may have been effective in some countries. In others, the situation may well have deteriorated further in the course of the 1990s. This, at least, is the impression gained from a survey of the conditions of primary schools conducted in 14 of the least-developed countries in 1995 (Postlethwaite, 1998). In significant parts of our world, primary education for all still constitutes a vision rather than a reality.

Educational Learning Theory

Abstract

A broad orientation to the principles and mechanisms underlying three major views of learning, namely, the behavioral perspective, the cognitive perspective, and the sociocultural perspective are presented. The focuses are on how these perspectives differ in their grounding assumptions and beliefs on how learning occurs and what constitutes the results or products of learning, as well as their impacts on research, practices, and educational policies.

This article presents a broad orientation to the principles and mechanisms underlying different views of learning, with an emphasis on how different representations of learning have affected and will continue to affect educational research and practice.

A brief account of the development trends of the paradigms of learning is first presented. Three major perspectives of learning are discussed, namely, the behavioral perspective, the cognitive perspective, and the sociocultural perspective. The focus is on how these perspectives differ in their assumptions and beliefs about how learning occurs, what constitutes the results or products of learning, and how they impact research and instructional approaches.

Introduction

Modern learning theories originated in the behavioral view of learning, which took a straightforward approach to learning as a stimulus–response relationship. The behavioral perspective on learning has been applied in many educational settings since the 1920s. Instructional strategies that are now widely adopted in classrooms, specifically those of classroom management and behavioral modification, are rooted in behavioral principles. How the mind makes it possible to understand, know, and think became a revolutionary focus in the 1950s as cognitivism challenged the behavioral view of the mind as a 'blank slate.' The cognitive perspective views knowledge as the key learning outcome. In learning, cognitive processes and functioning determine knowledge acquisition and construction. Cognitive processes are, therefore, important for educators to know and to incorporate into the design of instruction to best facilitate learning.

Learning can also be conceptualized as a socially engrained activity. Sociocultural perspectives have been used to explain this kind of learning. Modern learning theory recognizes that learning depends on the interaction of components within a developing system. In other words, learning depends on the maturation of the individual in his or her social context. As a consequence, research in educational learning theory seeks to understand the interactions between these components and the immediate and extended environment. Modern learning theories take into account the special educational needs of students with emotional and behavioral disorders, and those with the potential for exceptional academic achievement. Increasingly, research focuses on the link between learning needs and culture, particularly within the ethnically diverse classroom (Phillipson, 2011b). Hence, current research on learning recognizes the important contributions of parents, teachers, peers, and wider sociocultural influences and seeks to understand how the social environment can be manipulated to enhance learning outcomes. Table 1 gives an overview of the attributes of the behavioral, cognitive, and sociocultural learning theories.

The remaining sections elaborate on the three major paradigms in education, beginning with the behavioral and cognitive. This is followed by a description of the sociocultural view. The final section describes individual differences underlying learning processes and learning outcomes. The article closes with a brief account of current trends and related educational policies.

The Behavioral Perspective: Learning as Responding to Environmental Stimuli

Behaviorism, which originated in psychology, asserts all human behaviors result from interacting with the environment. Behaviorists regard a learning outcome as a relatively permanent change in a person's behavior caused by environmental influences such as experience or practice. J.B. Watson (1878–1958), an American psychologist and the founder of behaviorism, regarded learning as fundamentally physiological and mechanistic. In other words, learning is an automatic and involuntary reaction to external stimuli. Later, B.F. Skinner (1904–90) expanded the behavioral perspective of learning into the investigation of voluntary action. What is central to both involuntary and voluntary learning is the rejection of introspective examination of the mind; cognition, feeling, purpose, aim, and will are excluded in seeking to understand the mechanism of how we learn, as these internal processes cannot be publicly observed, controlled, and studied. This view encouraged and emphasized the importance of formulating principles of learning through the empirical study of observable behavior.

Pavlov's theory of classical conditioning and Skinner's operant conditioning characterized the behavioral principles of learning involuntary and voluntary actions respectively. They both describe the stimulus–response relationship that results in a person learning to perform an act or to respond in a certain

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92150-0

Table 1 Overview of the three major learning theories

	Paradigm		
	Behavioral	*Cognitive*	*Sociocultural*
Principles of learning	Learning occurs as a result of stimulus–response relationship. Motivation to learn comes from external sources. Internal mental processes are irrelevant.	Learning occurs as a result of the development of cognitive abilities and use of cognitive strategies in remembering, integrating, and making sense of the world. Learning might take place without observable changes.	Learning occurs as a result of the maturation of an individual in his or her social context through interaction with others who are more skilled and knowledgeable in the system. Learning takes place in reciprocal conditions.
Factors affecting learning	Environmental influences, reward, punishment, etc.	Cognitive development, environmental influences, cognitive strategies, beliefs, self-efficacy, etc.	Cognitive development, significant other environmental influences, cognitive strategies, beliefs, etc.
Role of learners	Passive and have little awareness of the learning process	Engage mentally in active and purposeful construction of new information and experience	Engage with others and the environment in active and purposeful construction of new information and experience
Products of learning	Overt behavior changes	Intellectual growth and knowledge acquired	Intellectual growth, adaptation to the environment, and knowledge acquired
Key theories	Classical conditioning (Pavlov), operant conditioning (Skinner)	Model of cognitive development (Piaget), information processing theory (Atkinson and Shiffrin), levels of processing (Craik and Lockhart)	Zone of proximal development (Vygotsky), cultural behavior (Wertsch), apprenticeship (Rogoff), ecological system (Bronfenbrenner), social cognitive theory (Bandura)
Educational implications	Widely adopted in creating learning environment that shapes behavior in desirable ways; strategies derived include token economy, response cost, and time-out procedures, etc.	Essential to contemporary understanding of how learners store, retain, and reason information; allow educators to create pedagogical strategies that facilitate the organization and transmission of knowledge	Widely adopted as effective ways in structuring learning where teachers are active facilitators in scaffolding strategies in classroom teaching and assessments; pedagogical strategies target individuals to reach his or her potential in learning.

way. In particular, commonly used strategies, such as the token economy, response cost, and time-out procedures, arise from the theory of operant conditioning. These strategies aim at managing observable behaviors through consequences. If applied consistently, they can be effective and powerful in inducing learning motivation and modifying inappropriate behaviors.

Involuntary Learning: The Theory of Classical Conditioning

Classical conditioning demonstrated involuntary or reflexive learning through association with stimuli. The founder of the theory, Ivan Pavlov (1849–1936), was a Nobel Prize-winning Russian physiologist and neurologist whose earlier research focused on involuntary reflexes of animals and later extended to children. In Pavlov's (1927) experiment on animals' digestive systems, he found that dogs learned to salivate when the sound of a bell was repeatedly paired with the presentation of food. Later, the learned response to salivate upon the sound of the bell continued even without the presentation of food. This automatic form of learning is what is called 'conditioning.' Watson extended Pavlov's finding into the study of more complex reflexes, such as emotional response. In a controversial experiment, he conditioned a young child named Albert to develop a fear of rats and objects that resembled them.

In education, the theory of classical conditioning provides the basis for understanding and treating test anxiety, school phobia, and similar conditions. For instance, test anxiety is a physiological response that can be unlearned if the presentation of tests is repeatedly associated with a stimulus that elicits pleasant emotion in students (Legge and Harari, 2000); teachers should consistently present nonthreatening testing environments to induce a positive reaction in their students.

Voluntary Learning: The Theory of Operant Conditioning

The word 'operant' refers to what we do to operate and function. Edward Thorndike (1894–1949) formulated the Law of Effect, which states that a positive consequence will lead to repetition of a behavior and that a negative one will discourage a behavior from being repeated. This stimulus (consequence)–response association forms the basic mechanism behind operant conditioning. The theory, which was named by Skinner in 1930s, describes the effect of consequences on the learning of voluntary behaviors. Based on the principle that a behavior is contingent on the desirability of consequences, two concepts are central to operant conditioning: reinforcement and punishment.

Strengthening a Behavior

Reinforcement is the addition of desirable, or the removal of undesirable, stimuli from the environment immediately after a behavior is performed so as to cause the particular behavior to happen again. Academic performance can be reinforced by praise, teacher recognition, opportunity to engage in a certain school activity, and tangible rewards such as food and prizes. The same reinforcer may not appeal to all students. For instance, the token economy is a reinforcement strategy whereby students are rewarded with a token (e.g., a sticker) that can be used to exchange things with an inherent value, such as extra activity time or access to computer learning materials. In contrast, the strategy of response cost involves taking away an earned reward for misbehavior. It maximizes the effect of a reinforcer when used in conjunction with the token economy. Providing reinforcement at the right time is the key to sustaining a learned behavior. In general, reinforcement needs to be provided consistently. Yet the schedule of reinforcement can also be varied in terms of interval or ratio so that a behavior is not reinforced every time.

Recent research has been exploring the effect of a combination of adding desirable and removing undesirable stimuli on task performance (Bouxsein et al., 2011). Moreover, research has also begun to examine the physical and neurological effects of reward and punishment on learning different tasks.

Weakening a Behavior

In contrast, punishment reduces the probability of a behavior being repeated. When a behavior is followed by an unpleasant stimulus (e.g., public reprimand), or when a pleasant stimulus is removed (e.g., recess time), the behavior is less likely to happen again. Although punishment can immediately stop or suppress a behavior, it can instill fear, anxiety, and avoidance of the punisher. A popular strategy that is used by teachers and psychologists to modify disruptive classroom behaviors in young students is the time-out. A time-out is a form of punishment whereby a student is temporarily removed from an environment that reinforces a bad behavior. There are several ways to impose a time-out, and factors such as its duration, the location, and the student's understanding of the reasons underlying the time-out may affect its effectiveness.

Punishment is not considered effective for promoting learning as it very often leads to negative emotions, which are counterproductive to learning (Baumrind, 1997). Psychologists have called for caution in using physical punishment on young children as it could lead to aggressive behaviors in childhood and adulthood. Meta-analyses (Gershoff, 2002) on parental punishment and children's behavior have revealed that parental corporal punishment is related to higher levels of immediate compliance, but also to aggression and lower levels of moral internalization.

The Cognitive Perspective: Learning as Mental Operations and Reasoning of Information

The study of cognition can be traced to Gestalt psychology in the late nineteenth century – a school of psychology that studied how the mind perceives and organizes pieces of information into a structured whole, and derives from it a meaningful representation of the world. Leading cognitivists Jean Piaget (1896–1980), George Miller (1920–2012), Allen Newell (1927–92), and Herbert Simon (1916–2001) argued that mental activities define a human as an active learner who selects, filters, evaluates, and predicts according to his or her needs and goals.

Cognitive learning theories demonstrate a variety of types of cognitive functioning including how we remember, how

new information is integrated with prior knowledge to create new knowledge, how cognition develops, and how meaningful learning occurs. Together, they exert a strong influence on modern education as they reveal how knowledge is transmitted from teachers to students, and how students transfer knowledge from one domain to solve new problems in another.

Knowledge Acquisition

Piaget's view on human cognition has greatly influenced educators' understanding of children's minds. When a child learns, he or she navigates the world through two mutually dependent processes: assimilation and accommodation. In assimilation, previously learned information is used to make sense of new information. When the new information fails to fit in to existing understanding, accommodation takes place by altering and adding to prior understanding. In addition, the acquisition of knowledge requires our mind's readiness. Piaget's (1970) model of cognitive development describes children's changes in cognitive functioning as they grow. He regarded human cognitive advancement as a function of biological maturation and proper environmental stimulation. There are individual differences in the speed of development yet all children go through universal stages in the same sequence. Each of Piaget's stages (sensorimotor, preoperational, concrete operational, and formal operational) presents distinct cognitive characteristics for teachers to take into consideration when preparing learning materials. For instance, abstract mental manipulation does not take place until the child has reached the formal operational stage (around 11 years of age); hence mathematical and logical operations that require deductive inferences are not within the developmental stage of very young children. Piaget's model highlights the importance of teaching children what is within their developmental stage. He opposed teaching children beyond their mental capability.

Knowledge acquired must be properly retained for effective retrieval and application. The analogy of how a computer works best describes how the mind processes information. Atkinson and Shiffrin's (1968) multistore model describes a three-stage information-processing sequence of encoding, storage, and retrieval. As human memory is selective and has a limited storage capacity, instructional aids have been designed to facilitate the transformation of information into long-term storage. For instance, students' attention can be engaged by combining visual and verbal forms of teaching materials and using advance organizers that enable teachers to present information in hierarchical and graphical ways that would enable students to sort through what is relevant and what is not. The use of analogies and concept maps is also helpful for making connections between new and prior concepts explicit and concrete.

Teaching to Facilitate Knowledge Construction

The levels of processing theory, proposed by Craik and Lockhart (1972), describe knowledge retention as a function of the depth of analysis. Elaborated perceptual analysis results in less forgetting. Material that relates to a person's own interests is better memorized and more effectively transferred to the solving of new problems. Therefore, learning materials must be understood in a meaningful manner, and not through mere repetition, if true learning is to take place. This view has prompted modern education to move from knowledge retention to knowledge construction. The nature of knowledge construction is purposeful and dynamic, with the aim for students to reason about subject knowledge critically and independently. Its process emphasizes the integration of new information with prior knowledge, metacognitive controls, and strategic use of cognitive skills.

The traditional direct instructional method has been challenged by inquiry-based learning (see Dewey, 1938; Lashley et al., 2002), which encompasses many instructional strategies, including, but not limited to, inquiry learning, expository learning, discovery learning, problem-based learning, and experiential learning. These modes of learning are characterized by elements of collaborative learning activities, investigation of ill-structured problems, hands-on field experience, and an interactive classroom context. These elements call for students to work together to define, examine, analyze, evaluate, and present their own ideas. This practice allows students to use their higher order thinking skills to make decisions and judgments, and solve problems. At the core of inquiry-based learning is the principle that students as learners do not merely process and repeat information but actively make sense of it to generate new knowledge. The use of inquiry-based methods does not dismiss the significance of direct teaching as some base of knowledge must be taught systematically for inquiry-based learning to take place.

Constructing Beliefs about Knowledge

Students' conception about the nature of knowledge is essential to knowledge construction. Personal epistemology refers to a person's beliefs about and representation of the nature of knowledge and knowing. Kuhn (1992) has posited a developmental model that describes four stages of epistemological development: realist, absolutist, multiplist, and evaluativist. Kuhn's stages reflect a progression from an entirely objective regard of knowledge to an entirely subjective one, and eventually to a relative view of knowledge. In the early stages, learners rely on external sources to make decisions; those in the later stages view knowledge as less absolute and rigid. In line with Kuhn's model, a five-dimension model of epistemological beliefs developed by Schraw et al. (2002) is also commonly used instrument for assessing individual's personal epistemology. The five dimensions include *simple knowledge* (knowledge as isolated information vs complex), *certain knowledge* (knowledge as absolute vs tentative), *omniscient authority* (knowledge is drawn from authority), *quick learning* (learning occurs quickly or not at all), and *innate ability* (intelligence is a fixed entity). Together, they describe a person's understanding of what knowledge is and how it is acquired. Individuals with sophisticated beliefs of knowledge tend to hold a more open-minded view of conclusion and judgment, and would value more the use of reason and evidence in supporting one's point of view. Epistemological beliefs have been shown to influence students' approaches to argument analysis and critical thinking, and their academic performance.

Controlling Cognitive Processes

Efficacy in learning is a function of how much we learn as well as how we go about learning. Self-regulatory learning consists of monitoring, evaluating, and reflecting on one's task progress and performance. These strategies are called metacognitive strategies. Metacognition is the control of cognition (Flavell, 1979). It includes applying a set of metacognitive strategies to the use of cognitive skills on a given task. Self-regulatory learners devote their attention to completing the task to their best ability, make plans for how to go about completing a task, seek alternatives, and constantly evaluate their own path of thought. Self-regulatory learning can be developed in young children. Effective instruction should include guidelines on self-monitoring and reflect on the way to go about learning, which will help students to link the learning method, as opposed to ability, to performance. The responsibility of learning is borne by the learner, and supported by the teacher, which creates independent learners who are clear about their goals, strengths, and weaknesses, and strategic in their approach to learning.

The Sociocultural and Systems Perspectives: Learning as Social Interaction

Sociocultural theory highlights the importance of society's contribution to individual development by building upon the interaction between developing and learning individuals, and the society and culture in which they live. The basic assumption of sociocultural theory in relation to learning is that a learning context should be observed and interpreted in the broader social system in which the learning is taking place. This would allow a sociocultural theorist to understand an individual's thinking and learning based on his or her participation in a socially and culturally integrated activity. Sociocultural theory draws from Lev Vygotsky's (1896–1934) work from the early 1930s, which has been elaborated on by theorists such as Aleksei Leontiv (1903–79), James Wertsch (1985), Michael Cole (2010), Harry Daniels (2001, 2008), and Barbara Rogoff.

Parallel to sociocultural theory is the system type of approach to learning, specifically the Bronfenbrenner model and the social imitation theory of social cognitive theory. These two theories again make society the nesting place where interactions or links established within a society provide the basis for learning.

Sociocultural Theory

Sociocultural theory, according to Vygotsky, requires the researcher to probe the environment surrounding students in order to understand their mental development. Two overlapping aspects of Vygotsky's sociocultural theory are important for the purposes of explaining learning: the observation of students' cognition within a sociocultural plane; and mediation and internalization, which take place between the social environment and the individual to facilitate learning and development.

Vygotsky (1978: p. 57) viewed students' cognitive development as existing on two planes: the social or 'between the people' plane, and the individual or 'inside the child' plane. The 'between the people' or interpsychological plane is the catalyst of the development of students' higher mental functions. The interpsychological plane is the platform for the development of mental functions through social interactions, which take place between students and other people who are more competent, including parents and peers.

The way in which a student learns and develops is determined by mediation between the student's psychological self and his or her social or cultural environment. Vygotsky (1978) regarded mediation as central to the acquisition and progression of students' higher mental functions. Mediation occurs initially between the student and the social plane, and is followed by internalization within the student's intrapersonal self. Together with signs and symbols, language is seen as a tool of culture and psychology that is part of the mediation process.

Vygotsky argued that mediation and internalization exposed students to 'mature cultural forms of behavior' that linked the external and internal planes in a 'genetic' relationship. In practice, this means that parents, teachers, peers, and others who have more knowledge and experience of the sociocultural environment become filters for students' learning and cognitive development. With guidance and instructions from more skilled partners, students can then absorb and internalize the information and thinking tools provided to them at different levels and in different ways.

Neo-Vygotskians such as Wertsch and Rogoff extended the premises of learning that happens on the social and personal planes to include aspects of cultural behavior and apprenticeship, respectively.

Wertsch used Vygotsky's thesis to demonstrate that without the social and cultural interaction, minimal learning happens. Wertsch, however, illustrated the learning that happens in classrooms. He showed that the cultural aspects of language and the associated psychological tools or mediatory individuals such as teacher or parent mediate classroom learning. Wertsch demonstrated that when language and cultural competence are integrated into learning, optimal learning results (Wertsch, 2007).

Rogoff expanded Vygotsky's thesis of the significant other in the process of learning. Rogoff's research centered on the idea that a young apprentice could learn constructively and productively by being mentored (Rogoff, 1990). Rogoff also showed how apprentice learning could happen on the social, personal, and institutional planes. She stressed that for learning to happen, the interaction between apprentice and mentor must transcend the social and personal within the institutions from which they are learning.

Research using sociocultural theory as a framework has adopted two approaches to explain the interactional and mediatory aspects of the learning process. The first approach is observation of the processes between student and teacher within the learning context. Through her intrapersonal, interpersonal, and cultural lenses, Rogoff applied the methodology of observation as a valid method of documenting learning. Other researchers have used statistical modeling to show the mediation process of learning. This is usually the case when the learning is within a context that has embedded social, cultural, and personal planes.

Bronfenbrenner's Ecological System

In Urie Bronfenbrenner's (1979) bioecological systems theory, it is possible to see the influence of Vygotsky's sociocultural theory where the child's social setting is an important aspect of his or her development. Bronfenbrenner's model focuses on the child and interactions between the child and the various social contexts. Some of these interactions will encourage the child's learning; others will inhibit it.

This system theory is represented as a series of environmental levels with the child in the first level known as the microsystem, which represents the most direct influences on the child's development. In addition to biological factors, these factors include the child's family, friends, classmates, and teachers. Here, interactions add to the child's experiences and development, which in turn affects the people around the child.

The next level, the mesosystem, represents the interactions among the components of the microsystem. For example, parents and teachers may work together to support the child's education. However, the child's immediate friends or classmates may discourage the child from participating in school.

The third environmental level is the exosystem, which describes the link between the child's immediate contacts and the social setting of these contacts. For example, the child's teacher attends a university course as part of his or her continuing professional development and learns about a new teaching strategy that may indirectly affect the child's learning experience. Other elements in the exosystem are the interaction between the child's parents and the parents' occupations.

The final level in the model is the chronosystem. This level explains the changes that occur over time. For example, the parents may divorce and remarry, the child moves from Grade 2 to Grade 3, or there are political or social changes in the country where the child lives.

Social Cognitive Theory

Albert Bandura's (1971) social cognitive theory explains how children can learn by imitating other modeled behaviors through reciprocal interaction among cognitive, behavioral, and environmental influences. Bandura stressed that for learning to occur, several cognitive and affective elements must exist in the reciprocal interaction of modeling between a person such as a teacher and a child as a student. These elements are attention paid to learning, retention of what is remembered and learned, reproduction or application of learned concepts, and the motivation or intention to learn (Bandura, 2001).

Similar to Vygotsky's view of dynamic interaction, Bandura believed in 'reciprocal determinism,' which assumes that a person's behavior is a result of his or her social world and that the world is a result of that person's behavior and action. Ultimately, when we think of learning in terms of Bandura's theory, we see it as a consequence of one's attention to what is being taught and one's intention to remember what is attended to. Following on from this is the person's motivation to learn and ability to apply what is learned. In many instances, this is seen as an imitation process of the person who is teaching by the person who is being taught.

Educational Implications of Sociocultural Perspectives

Vygotsky suggested that meaningful and dynamic instructions that form the social and cultural nature of interactive and reciprocal learning encourage the psychological development of a child. From this notion, Vygotsky conceptualized the zone of proximal development (ZPD), which is the difference between a child's 'actual development level as determined by independent problem solving' and the increased level of "potential development as determined through problem solving under adult guidance or in collaboration with more capable peers" (Vygotsky, 1978: p. 86). The ZPD focuses on the interaction of learning and development that emphasizes thinking and speech as two essential components of verbal thought that dynamically work together for children to make meaning and sense during the learning process.

Vygotsky (1960) saw the dynamic activity as a social process where the participants bring to the process their own knowledge and experience. He suggested that children are capable of solving problems beyond their actual developmental level or of engaging in higher order thinking when interacting with a teacher or parent. This process can also be situated within the imitation process of social cognitive theory and the broader system process. From this notion, dynamic assessment is a probing procedure that is constructed on an empirical assumption that the beginning and the last levels of a learning task are better remembered and learned than the ones in the middle. Structured scaffolding or hinting and probing take place when a student fails at each level of learning task until retaining enough of the learning to reach the next level or his or her full potential.

Individual Differences in Learning

Differences in educational outcomes might be attributable to individual differences in intelligence, creativity, motivation, and aspects of *self* such as self-concept, self-esteem, and self-efficacy. Research concerning the bases of individual differences has been highly influential in education. For example, Strenze (2007) concluded that psychometric (g) intelligence is a powerful predictor of educational, occupational, and financial success. Although teachers do not routinely test their students' intelligence, a number of alternative models of intelligence, such as Howard Gardner's multiple intelligence theory, have become popular among educators because they are inclusive and can provide a framework for curriculum development.

Creativity research notes the link between cognition and learning. Gelman and Gottfried (2006), for example, have argued that creative processes are necessary for the development of language and the construction of new knowledge.

Many models of learning are based on the relationship between *academic* self-concept, self-esteem, self-efficacy, and academic achievement (Hattie, 2009). Hattie concluded that academic self-concept and self-efficacy begin with past academic achievement, but that self-esteem does not. In the classroom, teachers focus on raising the academic self-concept and self-esteem of students.

Achievement goal theory focuses on the relationships between goal type (learning goals and performance goals),

cognitive processes, and academic achievement. Although there is broad agreement that learning goals lead to better educational outcomes, research suggests that performance goals can also be effective, particularly for Chinese students (Phillipson, 2011a). The causal link between the classroom structure and the development of the different goal orientations is an important area of educational research.

Changing Paradigms and Related Educational Policies

Educational policies are based on paradigms of 'quality' education, with quality defined in terms of economic indicators such as efficiency, effectiveness, economy and accountability, and educational outcomes. The development of educational policy is influenced not only by our understanding of the psychology of learning but also by advances in the psychometric instruments that measure student learning. For example, the No Child Left Behind Act of 2001 in the United States relies on research on psychometrics to define standards and to measure student academic achievement.

Educational systems around the world are more responsive than ever to international tests of academic achievement, including the Program for International Student Assessment, coordinated by the Organization for Economic Co-operation and Development, and the Progress in International Reading Literacy Study and Trends in International Mathematics and Science Study, both coordinated by the International Association for the Evaluation of Educational Achievement. Again, the results of these tests impact the development of educational systems and policy on student achievement, and are dependent on advances in psychometrics.

In response to these changing paradigms, many educational systems are implementing educational reforms. In Hong Kong, for example, these reforms include a reorganization of the secondary and tertiary school structure, the reintroduction of Liberal Studies into the curriculum, the adoption of an outcomes-based curriculum, and the selective implementation of English as the medium of instruction. In broad terms, the purpose of these reforms is to enable all students to 'develop their potentials (sic) and lead a rich life in the new century' and places no numerical limit on the number of students capable of achieving exceptional levels of performance.

With a greater focus on accountability in education, teachers have become increasingly aware of the importance of research about assessment theory. With a foundation in statistics, educational assessment takes into account the validity and reliability of assessment results and the need for measurement objectivity. Accordingly, many teacher education courses include training in assessment theory and practice, and advances in item response theories such as Rasch modeling.

Modern learning theories have recognized that learning outcomes are affected by the interactions between students and their immediate and wider environments. Based on Bronfenbrenner's bioecological systems theory of human development, the immediate environment includes peers, parents, and teachers. Attempts to model the interactions between students and their environment include systems models of learning such as Ziegler's (2005) actiotope model of giftedness (AMG). Although focusing on the development of exceptionality, the AMG can be used to understand the impact of the environment on academic achievement more broadly as well as to identify the basis of underachievement. In particular, the AMG integrates research across a number of paradigms, including motivation; aspects of 'self' such as self-concept, self-esteem, and self-efficacy; and the educational and cultural environment.

Hattie's (2009) meta-analysis of the effects of influence on student learning concluded that the most important predictors of student learning originated from the teacher, including feedback related to attributions of success, instructional quality and type, and classroom environment. In terms of learners, the most important predictor of student learning apart from past success was their learning disposition. At the same time, parental expectations of academic achievement were the most important predictor of learning originating from the home. However, the discrepancy between research and classroom practice is often significant, and teacher education programs need to strengthen the relationship between research and practice. In addition, mechanisms need to be developed to ensure that teachers remain cognizant of research on learning.

Abstract

Using mass forms of media for educational purposes is not a new idea. Mass media have been used for centuries to deliver educational content to children. From penny books, film projectors, radios, televisions, cassette recorders, and video machines to newer forms of media like computers, CD-ROMS and DVDs, the Internet, tablets (e.g., iPads), and mobile devices (e.g., smart phones), mass media have been introduced, enthused over by some advocates for their ability to reform education, and bemoaned by others who argue that mass media have led to declining educational and moral standards. This article reviews research, theories, and controversies concerning the use of mass media in educational settings, investigates a few well-known cases (e.g., Sesame Street), and summarizes current and emerging directions for further research.

Introduction

Using mass forms of media for educational purposes is not a new idea (Fisch, 2012; Wartella and Robb, 2008). Mass media have been used for centuries to deliver educational content to children. From penny books, film projectors, radios, televisions, cassette recorders, and video machines to newer forms of media like computers, CD-ROMS and DVDs, the Internet, tablets (e.g., iPads), and mobile devices (e.g., smart phones), mass media have been introduced, enthused over by some advocates for their ability to reform education, and bemoaned by others who argue that mass media have led to declining educational and moral standards. Marshal McLuhan wrote in 1964 that "Each new technology creates an environment that is itself regarded as corrupt and degrading. Yet the new one turns its predecessor into an art form" (p. ix). Media are a pervasive part of children's lives. Children under 8 years of age spend just over 3 h per day using media (Commonsense Media, 2011), while children between 8 and 18 years of age spend 7.5 h per day with media when multitasking is considered (Rideout et al., 2010). In recent years, there has been an explosion of media across multiple platforms.

Definitions of Educational Media

Educational media include media designed to intentionally or incidentally educate or enlighten (Kirkorian and Anderson, 2008). At present, there is no consensus or federally constructed definition of educational media; however, a definition for educational television that was developed as part of the creation of the Children's Television Act of 1990 (CTA) is a useful starting point. The CTA was created by the Congress in response to data indicating that children spend more than 3 h per day watching TV and that there is clear evidence that exposure to TV influences their development. The CTA states that "core programming [should be] specifically designed to serve the educational and informational needs of children 16 years of age and under, including the child's intellectual/cognitive or social/emotional needs" and must serve "the educational and informational needs of children as a significant purpose" (CTA, 1990). Advocates of the use of media as a potential learning tool argue that all media content is educational; that is, children will learn from whatever content with which they engage regardless of the format through which it is delivered (e.g., Skoll et al., 2006). For instance, there is considerable evidence that using or viewing violent media content (e.g., violent TV programs or video games) is associated with violent and aggressive behavior (e.g., Anderson and Bushman, 2001). Educational media, on the other hand, are typically created with the purpose to educate and inform. As such, research reviewed in this article must be specific to media that are "intentionally curriculum-driven with a deliberate plan to teach" (Kirkorian and Anderson, 2008: p. 188).

The CTA definition is purposely broad. It is much more elusive to define what characteristics make a product labeled 'educational' both high quality and effective. Jordan and Woodward (1997) defined the quality of children's educational television using six criteria created in consultation with experts in the field as well as after a review of research findings indicating that programs designed to be educational are generally beneficial to children. These criteria include:

1. Lesson clarity: how directly or explicitly the primary lesson is presented.
2. Lesson integration: the extent to which the primary lesson is repeated or incorporated throughout the program.
3. Lesson involvement: the extent to which the primary lesson is engaging and absorbing.
4. Lesson applicability: the extent to which the primary lesson is shown to be connected to the real world.
5. Lesson importance: the overall value or usefulness of the primary lesson.
6. Lesson reinforcement: the extent to which learning (including effort and mastery) of the lesson is rewarded within the episode.

Other advocacy organizations and researchers have adapted both the CTA language and these criteria for multiple media forms. For instance, Common Sense Media, an organization whose mission is to improve the lives of kids and families by providing trustworthy information about media to parents and educators, uses these definitions to evaluate content across TV,

video games, computer games, Internet sites, and mobile applications (see http://www.commonsensemedia.org/about-us/our-mission/about-our-ratings). Within a research context, Barr and Linebarger (2010) defined media as educational if the product materials made some type of educational claim. Educational claims were defined as visual or verbal content on packaging, product Web sites, and other product materials that suggested exposure to a particular product "could assist children in learning important information, skills, values, and behavior while entertaining them and exciting their curiosity to learn" (CTA, 1990: p. 303a; Fenstermacher et al., 2010: p. 561). This definition was used as a guide for the selection of materials that the creators of that content deemed educational whether or not evidence existed to support such claims. This was done purposely with the intent that these 'claims' would be further analyzed to evaluate whether the program content both matched the claims and matched the ways in which young children were known to learn best.

Models and Theories of Learning from Educational Media

The process of acquiring new information from media is a complex one involving attention to and subsequent comprehension of these stimuli. When children interact with media, they integrate the various stimuli into meaningful, comprehensible bits of information by attending to important or interesting aspects of the stimuli (Huston and Wright, 1989). Although a great deal of knowledge about young children has been gained from past research on media use individually, the obvious step of merging the ways in which media technologies are used for learning to understand and enhance cognitive development is limited. Models of learning developed from the television literature provide a useful framework for understanding how media might impact children's attention and learning through media.

Anderson and his colleagues (Anderson and Lorch, 1983; Anderson et al., 1981) proposed a model of attention to television where perceptually salient features of the stimulus initially draw a child's attention to the screen. When a child has little experience with television, sounds and unusual visual effects trigger the basic orienting mechanisms built into the perceptual system (Miron et al., 2001). These production techniques ('formal features') provide structure and give meaning to the sensory images contained in the programs (Calvert et al., 1982; Campbell et al., 1987). Comprehension is then improved when formal features are used to denote key moments and critical content for young children's focal attention.

Formal features constitute the means by which information is conveyed in a particular medium that, in turn, influences how that information is processed (Neuman, 1995). For television, the symbol system comprises perceptually salient events (i.e., sound effects, loud music, and rapid cuts), reflection (e.g., long zooms, singing, and moderate levels of physical activity), and character dialogue or speech (e.g., female or peculiar voices; Calvert et al., 1982; Huston and Wright, 1997). For computer and mobile gaming applications, the symbol system includes icons for repetitive functions (e.g., go back, save, help), navigational elements, music, animations during transitions from one state to another, drop-down menus, etc. For console video games, the symbol system includes the input device and its associated components (e.g., for XBox, the controller includes buttons labeled A, B, X, and Y), setup requirements (things that must be done once at the beginning of a game), the progression of play (what happens during game play including the leveling system), and resolution (what conditions cause the game to end, how an outcome is determined based on the game state).

Symbol systems are carriers of information; however, once the individual has received the perceptually salient and relevant stimuli, information will be processed similarly across media. Initially, children are more dependent on a medium's symbol system for decoding purposes. For example, children who are beginning to read spend enormous amounts of time learning the correspondence between printed letters and word recognition. Once children have learned to decode efficiently (when decoding has become automatic), they can read for content. Media operate in the same manner. Children must learn some rules about the forms to become efficient processors of its messages (Huston and Wright, 1983). Therefore, Salomon (1979) proposed that symbol systems might play a role initially, at lower levels of processing. As children become adept at using a medium's symbol system, the same kinds of higher-order cognitive skills used effectively in other media will then be used for deeper processing in their most recently mastered medium.

Huston and Wright (1989) and Rice et al. (1982) proposed a model of attention that elaborates this idea (see **Figure 1**). At various points while viewing a program, children make a series of attentional decisions. These decisions are based on cues of perceptual salience, comprehensibility of the program, and interpretability of the content. This model also predicts that attention is a joint function of the stimulus features, both form and content, and the dispositions of the viewer, including experience with the material, the medium, and general world knowledge. Interest and attention are a function of the stimulus characteristics. A stimulus perceived as "moderately novel, of intermediate complexity, integratable, somewhat regular, partially ordered, and recognizable" (Huston and Wright, 1989: p. 117) should elicit the greatest amounts of interest and attention. When the stimulus characteristics no longer arouse interest or attention because of familiarization and habituation (i.e., familiar, simple, wholistic, redundant, repetitive, and expected), children no longer attend to them. Likewise, if the stimulus characteristics fall at the incomprehensible end of these continua (i.e., novel, complex, incongruous, inconsistent, unpredictable, and surprising), children will not attend because the stimulus is immediately perceived as incomprehensible. High-end stimuli become more familiar and hence more comprehensible with repetition and thus gain attention while the low-end stimuli undergo further habituation with repetition and thus lose attention. The resultant of these two kinds of changes over time is that the high point of interest and attention slowly migrate toward the higher end. With age and viewing experience, the child's focus will continually move toward more cognitively challenging stimuli, hence the stimuli that are initially incomprehensible will "gradually move toward and through the child's focal lens of

Figure 1 Traveling lens model. Reproduced from Rice, M.L., Huston, A.C., Wright, J.C., 1982. The forms and codes of television: effects of children's attention, comprehension, and social behavior. In: Pearl, D., Bouthilet, L., Lazar, L. (Eds.), Television and Behavior: Ten Years of Scientific Progress and Implications for the Eighties. US Government Printing Office, Washington, DC, pp. 24–38.

maximum interest, and then lose attention as they are habituated and become old hat" (Huston and Wright, 1989: p. 118).

In addition to these processing models of media, there are two media-specific theories of how children learn from media, both with roots in information-processing approasches: Fisch's Capacity Model (2000, 2004) and Mayer and Moreno's Cognitive Theory of Multimedia Learning (CTLM, 2003). Broadly, these two theories focus on the sequence and execution of cognitive events that occur when children are engaged with media. Children attend to environmental stimuli, encode these stimuli as information, store the new information in memory, and subsequently retrieve this information when needed.

Originally developed from the empirical base of studies examining learning from educational television, Fisch's Capacity Model (2000, 2004) proposes that the sequence and execution of cognitive events are influenced by two forms of content: narrative (i.e., storyline) and educational (i.e., intended lesson). Information-processing approaches argue that working memory resources are limited. For effective processing, cognitive demands on working memory cannot exceed available resources. Cognitive demands come from three components of the media content: processing of narrative content, processing of educational content embedded within the narrative, and the distance between these two content types. The distance reflects the degree to which the educational content is tangential to or integral to the narrative. When tangential, both content types compete for limited working memory resources. Because the narrative content is easier to process, children will default to processing the narrative at the expense of processing the educational content. Conversely, when the content types are integral to one another (i.e., the educational content is embedded within the story and helps to advance the storyline), competition for working memory resources is reduced and children are more effective at processing both content types and learning the educational content. This model predicts that children will comprehend educational content more completely when the cognitive demands of processing both content types are low and when the distance between the content types is small.

An added difficulty arises when considering learning beyond the educational content embedded within the program, or transfer of learning to situations outside the original context. Transfer requires that the viewer learns the educational content within the program, constructs a mental representation of that content, and then applies that content in a novel situation (Bransford et al., 1999). Educational content that is overly contextualized when initially presented can impede transfer (Bransford and Schwartz, 1999). The capacity model argues for contextualization of educational content within the narrative (Fisch, 2004), creating difficulty in determining the best presentation of the educational content within the narrative. Fisch (2004) proposed that media content must be contextualized when presented, but that it could also be presented multiple times using varied formats across different contexts (referred to as 'varied practice'; e.g., Piotrowski et al., 2013).

Mayer and Moreno's (2003) Cognitive Theory of Multimedia Learning (CTML) describes learning from media using three assumptions of cognitive science: (1) there are two separate channels (visual/pictorial and verbal/auditory) for processing information; (2) each channel has a limited capacity; and (3) learning is an active process that entails filtering, selecting, organizing, and integrating information using prior knowledge. Learning from multimedia is a demanding process that requires five cognitive processes: selecting relevant words,

selecting relevant images, organizing those words to create a coherent verbal model, organizing the images to create a coherent pictorial model, and then integrating the verbal and pictorial models together as well as with prior knowledge (Mayer, 2005). Layered within these cognitive processes are five different forms that words and pictures assume depending on the stage of processing: (1) the words and pictures actually presented in the stimuli; (2) the acoustic and iconic representations of these words and pictures that a child holds in sensory memory; (3) sounds and images that a child selectively attends to and then holds in working memory to be acted upon (i.e., beginning of knowledge construction); (4) a verbal model and a pictorial model that a child constructs in working memory (i.e., the child organizes these two models into coherent representations and integrates them together); and (5) knowledge in long-term memory (i.e., prior knowledge a child possesses that is accessed and used to make sense of the incoming stimuli). Consequently, CTML predicts that children learn content more deeply and effectively when words and pictures are combined than when one or the other alone conveys content.

Both the Capacity Model and the CTML have been used to examine the cognitive processing associated with the integration of incoming stimuli and the constraints that are associated with working memory, as this processing relates to educational television specifically (Capacity Model) or multimedia texts more broadly (CTML). While both approaches predict that integration of incoming stimuli can be difficult as the complexity of the stimuli increase, the nature of stimulus complexity varies (see Fisch, 2012). The Capacity Model predicts that learning challenges arise from difficulties with integration of different types of content. Specifically, when the educational content or curriculum embedded in a TV program is not well linked to the narrative or storyline in that program, learners will default to the easier of the two content types (i.e., the storyline) at the expense of learning the educational content. In contrast, learner challenges predicted by CTML arise from difficulties in processing multiple streams of information received across multiple modalities (i.e., words, pictures). Because learners have a limited working memory, they are able to process only a few chunks of information at any one time. As the complexity and volume of both words and pictures increase, the ability to adequately process, store, and later retrieve information is degraded.

Knowledge Base on Learning from Educational Media

From the accumulated evidence, high-quality educational media can be powerful resources for learning. Areas where beneficial effects have been found include general cognitive skills, school readiness, language acquisition, literacy, math, science, civics, social studies, general knowledge, prosocial behavior, executive functioning, problem solving, creativity, etc. (see Fisch, 2004; for a detailed review). Across these domains, researchers have determined that understanding educational media effects involves understanding independently and in combination the ways in which a child's individual abilities and prior knowledge and experiences, attributes of the stimulus, and the environmental and contextual features that are available during the processing of a specific media content (e.g., Bandura, 2001; Barr and Linebarger, 2010; Huston and Wright, 1989; Linebarger and Vaala, 2010). This orientation to media effects examines learning as a set of cognitive processes in an effort to elucidate the causal mechanisms through which effects are produced (Barr and Linebarger, 2010; Clark, 1983; Dupré and Cartwright, 1988; Hedstrom and Ylikoski, 2010; Kozma, 1994; M. Mackey and E. Ellerman, personal communication, 12 August 2013). Media can then be divided according to the type of cognitive activity associated with its use: viewing (TV, DVDs), listening (music, audio books), interacting (computers, video games, cell phones, and applications), producing (digital video/camera), integrating (comprehensive intervention, transmedia storytelling), and understanding (issues with technology use in the classroom; M. Mackey and E. Ellerman, personal communication, 12 August 2013).

Examples of Learning from Educational Media

Media-based interventions may be designed broadly (e.g., to provide caregivers or parents with resources to promote literacy) or narrowly (e.g., to promote a particular topic such as nutrition; Fisch, 2004). These interventions typically combine ancillary materials (e.g., manipulatives, books, scripts, posters, puppets, felt boards, the Internet, or mobile applications) and teacher guides with various TV episodes from an educational series. The program acts as an anchor for the intervention. Because children have reported confidence in learning from television (e.g., Linebarger, 2001), coupling existing educational television programs with ancillary materials offers opportunities for enhanced learning. In the three cases described below, learning has been increased with the addition of intervention strategies. Subtle differences in the development of the materials can make a large difference. For instance, when creating materials for an intervention designed around Between the Lions (BTL), research demonstrated stronger effects when the materials were developed in collaboration with the target audience using both developmentally appropriate and culturally relevant materials (Linebarger and Wainwright, 2007a) compared with the materials developed in-house and given to the target audience (Prince et al., 2002). Although learning effects were found in both interventions, greater effects were associated with the more specifically tailored intervention. In other nonmedia interventions, this tailoring to the target audience also leads to more enhanced effects (Barrera and González Castro, 2006).

Sesame Street

In the late 1960s, Sesame Street was developed to serve the educational and social needs of preschool children, especially those living in poverty (Mielke, 1994) with great success (e.g., Wright et al., 2001), both in the United States and all over the world (Cole et al., 2001). The program was a pioneer in the field of educational media for several reasons. First, it is one of the few programs that created and implemented a detailed and comprehensive set of curricular goals. Second, it used research to inform the development of content to improve production (formative research) as well as to test the overall effectiveness of

the program (summative research). Over time, this program has been successful in helping generations of preschool children learn all sorts of skills ranging from the alphabet and numbers, to helping and empathy, and even self-regulation and executive functioning (e.g., Fisch and Truglio, 2001; Wright et al., 2001). These early advantages have also been longitudinally linked to adolescent outcomes. Specifically, early viewers of Sesame Street obtained better grades in high school, read more books for fun, reported greater academic self-concepts, and detailed fewer aggressive attitudes when compared with teens who rarely or never viewed Sesame Street at 5 years of age (Anderson et al., 2001).

Interventions involving Sesame Street vary from instructing the child to pay attention to particular content prior to viewing (Sell et al., 1995) to using sophisticated curricula involving episodes, books, and extension activities (Yotive and Fisch, 2001), texting Sesame Street-themed parenting tips, audio messages from Elmo, and literacy-related Sesame Street videos to parents' cell phones (Horowitz et al., 2006). Sell et al., (1995) randomly assigned children to conditions where they either received instruction prior to viewing or repeated viewings, or both. Previewing instruction did not influence children's comprehension or program content whereas repeated viewings were successful at helping children comprehend the plot. The authors suggested that repeatedly viewing the videotape allowed the children to process the content more effectively.

Outreach efforts involving Sesame Street were initially conducted to increase the viewership of the program. Once its popularity was firmly established, outreach projects changed from viewership efforts to educational enhancement. It was hoped that the popularity of Sesame Street characters could be exploited to deliver educational messages to the target audience more effectively than the show on its own. The Preschool Education Program was composed of the TV series, children's books related to the series, and developmentally appropriate activities related to the series and books. Activities included extensions of viewing and book-related experiences (e.g., equivalent words in different languages, foods from different cultures). In addition to the various materials, there was also a teacher training component to help providers learn about the materials and to discuss key elements of the program with other professionals. In addition, newsletters containing information regarding upcoming episodes were distributed on a regular basis to provide opportunities for providers to integrate the intervention into their daily activities. Limited research on the intervention provided evidence that it had an impact on both children and their providers (Yotive and Fisch, 2001). Specifically, the children's social behavior, motivation for learning, verbal skills, and early literacy skills improved from pre- to posttest. Providers reported more self-confidence and improved instructional skills, especially skills related to joint book-reading episodes. Growth in skills was greater for providers and children in home-based care situations when compared with center-based child care.

In recent years, Sesame Street has begun to investigate the use of new technologies to deliver content that targets both parents and their preschoolers. Parents reported that after receiving the tips and materials via their cell phones, they felt more competent at scaffolding their children's learning as well as greater enthusiasm for using such content (Horowitz et al., 2006). Sesame Street has always been on the leading edge of using media to promote young children's academic and social learning. Advances in mobile technologies are now making it possible to provide educational opportunities for learning and discovery in ways that capitalize on the integral nature of such technologies in people's lives (Shuler, 2009).

Between the Lions

In an initial examination of BTL, kindergarten children who watched the program performed significantly better on almost all outcome measures of reading achievement when compared to similar children who did not (Linebarger et al., 2004). Specifically, the kindergarten children who watched 17 episodes from the first season of BTL were able to identify more letters and read more words than those who did not. Their understanding of concepts of print was enhanced and their phonemic awareness and letter–sound correspondence skills, skills highly predictive of latter, fluent reading, were significantly accelerated over those who did not watch. BTL was also the focus of a study conducted by researchers in Mississippi (Prince et al., 2002). More than 50 teachers and nearly 1000 preschool, kindergarten, and first grade students from the Choctaw Indian Reservation and the Delta region of the state (i.e., children who were low income and/or English Language Learners (ELL) students) were assigned to either a treatment group (i.e., received videotapes and ancillary materials) or a control group (i.e., did not receive the materials; however, they might see the program on their local Public Broadcasting Service (PBS) station). This investigation differed from the initial evaluation in two important ways. First, the evaluation period lasted 9 months (vs just over 1 month in Kansas). In addition, this project combined extensive ancillary intervention materials, training, and follow-up (e.g., teachers' guides, handbooks, posters, a CD-ROM with content from the Web site, sets of classroom books and take-home books stickers, bookmarks, and information for parents) with videotapes of the episodes.

Researchers found children who watched half-hour episodes of BTL regularly, and whose teachers carried out related activities, significantly outperformed control groups on several key reading skills including knowledge of print conventions, identification of initial word sounds, ability to read nonsense words, and the ability to identify spoken vocabulary words (Prince et al., 2002). Important questions remained regarding its applicability for multiple subgroups of children in different contextual situations. Several implementation issues arose in this Mississippi project. For instance, although logs were kept, it is unclear how well these correlated with student outcomes as fidelity of implementation was not examined. Investigators did not systematically collect information regarding teachers' perceptions of the intervention materials or satisfaction with and usability of the materials. Finally, it is possible that training related to the delivery of the intervention was ineffective with some of the educators, especially the poorly trained child care providers. Considerable variation in training and education levels of teachers may have impacted teachers' ability to deliver an effective intervention. Again, these data were not formally collected.

Lessons learned from the first Mississippi study were resolved in several follow-up intervention studies. The original intervention materials were made primarily by BTL content creator. This posed problems when the materials were taken into the field that might have been avoided had the end users been more fully consulted during the process. BTL project staff worked closely with the local cosmmunities to develop more culturally sensitive and appropriate literacy materials. Teacher training was provided along with technical assistance and mentoring throughout the interventions. Children's skills improved in direct relation to the amount of intervention experienced for oral language knowledge, letter names, phonemic awareness (i.e., isolating sounds in words and blending words), and general literacy abilities (Linebarger and Wainwright, 2007; Linebarger and McMenamin, 2010).

The Ready to Learn Initiative

In recent research funded by the US Department of Education, researchers investigated the creation of a 'media-rich curriculum' comprised of multiple media properties and platforms (Penuel et al., in press). Researchers devised a 10-week early literacy curriculum that featured episodes of the preschool literacy series Super Why, smaller self-contained segments from both Sesame Street and BTL, books related to all program content, games created for the PBS Kids Web site, and teacher-led viewing and postviewing activities (e.g., pausing the video, reflecting on specific segments after viewing). Teachers received training, supplemental materials, and ongoing mentoring prior to and during implementation of the intervention. Preschoolers' knowledge of letter names, phonemic awareness, story and print concepts, and specific letters in their own names were significantly better for those in the media-rich curriculum compared with preschoolers in a science-oriented control curriculum (Penuel et al., 2009).

Changes in Focus/Emphasis over Time

With the introduction of most forms of mass media, there have been advocates for the power and reach of the new medium to cynics who argue that this new medium will promote intellectual passivity or social problems (Wartella and Robb, 2008). Most studies that investigate new forms of media examine how exposure alone without any differentiation by the content of that exposure affects developmental outcomes. This orientation resulted in a preponderance of research investigating the negative effects of media (e.g., aggression, obesity). Focusing on the media delivery system or platform (e.g., TV, educational application, book) leads to simple cause and effect explanations. In contrast, examining cognitive processing, content, the structural features used to convey that content, and the contexts surrounding use of media offer stronger explanatory models for observed effects (Anderson et al., 2001; Barr and Linebarger, 2010; Clark, 1983; Huston and Wright, 1983; Kozma, 1994; Metzger, 2009). Over time, there has been a greater emphasis on understanding which types of content support positive developmental outcomes and which types of content exacerbate negative developmental outcomes and whether and how individual differences coupled with the ways in which media are used mediate or moderate the relations between exposure and outcomes (e.g., Jordan, 2004; Linebarger and Vaala, 2010). As such, researchers are better able to describe the most effective ways to deliver content, who is more or less likely to learn this content and why, and whether the presence of certain features in the environment support or diminish learning.

Current and Emerging Directions in Theory and Research

Transmedia

Transmedia refers to 'across media.' It describes any number of possible relationships that might exist between and among the various media that constitute a contemporary entertainment franchise. Kinder (1991) referred to transmedia as the 'entertainment supersystem' that emerged around various TV-based media properties (e.g., Teenage Mutant Ninja Turtles). Transmedia storytelling extended the use of characters and properties to include the "systematic unfolding of elements of a story world across multiple media platforms, with each platform making a unique and original contribution to the experience as a whole" (Herr-Stephenson et al., 2013: p. 6). Content and characters are repeated and expanded across platforms. As described by Fisch (2004), these types of learning opportunities promote varied practice with specific content thereby increasing both content-specific learning as well as transfer of that learning to other situations or problems. Proponents for transmedia learning argue that content delivered via multiple platforms promotes additive comprehension because children attend to and learn content as they follow or track the same story across these different platforms (Herr-Stephenson et al., 2013; Jenkins, 2006). Transmedia differentiates itself from cross-media (use of other media platforms to deliver the same content) and multimedia (which uses multiple kinds of media like words, pictures, sounds, videos in a single package) in that the user is incited to search out dispersed content and reassemble it into a meaningful mental model. It requires a creative reworking of stories and experiences as children reimagine, play, and learn from the media culture surrounding them (Herr-Stephenson et al., 2013). Empirical evidence testing the effectiveness of a transmedia approach is limited. Fisch and colleagues reported that children's use of mathematical learning strategies after viewing and using online games linked to the children's program Cyberchase was more sophisticated and their use of problem-solving strategies was more consistent when compared with children who engaged only in gaming (Fisch et al., 2011). The authors argued that exposure to the characters in multiple modalities facilitated both content and character connections across the two platforms (Fisch et al., 2011).

A Focus on Neuroscience

Anderson and colleagues (Anderson, 2007; Anderson et al., 2006a,b) proposed that technological advances in methodologies like eye tracking and magnetic resonance imaging should be considered as potentials for investigating questions related to the study of children and media. Researchers have used eye-tracking techniques to investigate how children process

onscreen text (Scinto, 2001; Vaala et al., 2009); whether and how infants understand the use of audiovisual production techniques like cuts (Kirkorian et al., 2012); and as a means to understanding basic processing of program content (Flagg, 1978; Chernin and Linebarger, 2005). Magnetic resonance imaging has been used to investigate both children and adult's attentional and comprehension capabilities during online processing of media content (Anderson et al., 2006b) as well as their emotional responses to violent media content (Mathews et al., 2005; Murray et al., 2006; Weber et al., 2006). Anderson (2007) describes the inherent difficulties in using neuroscience techniques to investigate media use and media effects but also argues that the use of such techniques can explicate the influence of media on brain structure and function; promote new modes of thinking about the problems that media effects researchers face; and provide new perspectives on the influence of media on children.

Methodological Problems

Measuring Media Exposure

Media use is pervasive among children. Capturing both the quantity and quality of exposure to media is a fundamental yet challenging measurement problem. Without adequate media exposure measures, efforts to tie the amount of time exposed to different media forms and content types to various outcomes will be difficult (Jordan et al., 2007). Exposure data have been obtained via a number of assessment strategies including interviews with children (if old enough) or their parents and caregivers (e.g., Jordan et al., 2007), diaries (e.g., Lapierre et al., 2012), neurological and psychophysiological measures during exposure (e.g., Anderson et al., 2001; Anderson, 2007), experience sampling methods (e.g., Moreno et al., 2012), electronic monitoring systems (e.g., Christakis et al., 2009), and video or direct observation (Anderson and Field, 1991). There is limited but increasing research that systematically and empirically compares different methods of capturing exposure (e.g., Anderson and Field, 1991; Jordan et al., 2007). Researchers who use exposure assessments across a number of disciplines (e.g., media, environmental toxins, dietary intake, time use) advocate the use of different collection methods to validate data and reduce error in measurement (dos Santos Silva, 1999; Fave et al., 2009; Wartella et al., 2009; Vandewater and Lee, 2009) and suggest that researchers carefully consider how much detail in exposure is needed as well as the kinds of data needed to answer specific research questions (Vandewater and Lee, 2009).

Links to Databases and Software

Center on Media and Child Health

The Center on Media and Child Health (CMCH) at Children's Hospital Boston, Harvard Medical School, and Harvard School of Public Health is dedicated to understanding and responding to the effects of media on the physical, mental, and social health of children through research, translation, and education. CMCH created a searchable database to access scientific research on media effects. Available at: http://www.cmch.tv/research/searchcitations.asp.

Common Sense Media

An independent nonprofit organization dedicated to improving the lives of kids and families by providing trustworthy information needed to thrive in a world of media and technology. Available at http://www.commonsensemedia.org/.

Federal Communications Commission/CTA

Guide to the CTA and what is considered educational on TV. Available at http://www.fcc.gov/guides/childrens-educational-television.

Joan Ganz Cooney Center

The Joan Ganz Cooney Center is an independent research and innovation lab that focuses on the challenges of educating children in a rapidly changing media landscape. Available at http://www.joanganzcooneycenter.org.

PBS Parents

PBS Parents is a parent-directed resource containing information on child development, early learning, and educational media. Available at http://www.pbs.org/parents/.

Educational Philosophy

Gert Biesta, University of Luxembourg, Walferdange, Luxembourg

Abstract

While philosophy of education is in one sense as old as philosophy itself, it emerged as a particular specialism of educational and philosophical scholarship in the English-speaking world in the twentieth century. This article discusses the philosophical engagement with education through time, highlighting issues concerning the definition of its two key terms – philosophy and education – discussing some classics in the philosophical literature on education, in order to arrive at a sketch of the development of philosophy of education in the twentieth century.

Introduction

In her widely used book *Philosophy of Education*, the American philosopher of education Nel Noddings states that philosophy of education "is the philosophical study of education and its problems" (Noddings, 2012: xiii). "Philosophers of education," she writes, "study the problems of education from a philosophical perspective" (Noddings, 2012: xiv). She therefore concludes that the "subject matter [of philosophy of education] is *education*, and its methods are those of *philosophy*" (Noddings, 2012: xiii; emphasis added). While many would agree with this definition – and in a sense philosophy of education can be nothing but the philosophical study of education – it nonetheless raises a number of further questions. One question is what philosophy actually *is*, which has been an ongoing topic of debate ever since philosophy came into existence as a distinctive intellectual 'genre.' However, for the philosophy of education there is not only the question what philosophy is, but there is also the question of what education is or might be – and here again we find a wide array of answers, not in the least from those who see themselves as philosophers of education. Rather, therefore, than seeing philosophy of education as the philosophical study of education, it is more productive to see philosophy of education as the encounter between philosophical and educational thinking, and it is this line that I will pursue in what follows.

What 'Is' Philosophy?

To think of philosophy of education as an encounter between philosophy and education makes it necessary to say something about the meaning of both concepts, that of 'philosophy' and that of 'education.' Our contemporary – and as some might emphasize: Western idea of philosophy emerged in Greek civilization between about 600 and 150 BC. While the Greek word 'philosophy' originally had a rather broad meaning, referring to a thirst for learning or a thirst for education, over time it came to describe the more specific tradition of thinking and writing that we now recognize as philosophy. One common definition of philosophy – a literal translation of the word – is that of 'love of wisdom.' In the *Phaedrus*, a dialogue written by Plato (427–347 BC), we can find Socrates (439–399 BC) arguing for a distinction between, on the one hand, being wise and having knowledge of the truth, and, on the other hand, *aspiring to* wisdom, knowledge, and truth. Socrates then argues that only a god can be called wise in the former sense, so that human beings who aspire for wisdom, knowledge, and truth should more fittingly be called *lovers* of wisdom, that is, philosophers. This line of thought already hints at a prominent characteristic of contemporary philosophy, in that philosophers nowadays would seldom lay claim to having knowledge – in this regard the domain of philosophy and the domain of science have over time become clearly separated areas of intellectual activity – but rather see it as their task to raise critical questions about everyday and scientific beliefs and arguments and their underlying assumptions.

Behind the simple definition of philosophy of education as "the philosophical study of education and its problems" (Noddings) we can find a whole universe of philosophical ideas and traditions and of ways and styles of doing philosophy, which makes it quite difficult if not impossible to reduce this variety to some kind of 'essence' of what philosophy is or is about – which is one of the reasons why the American philosopher Richard Rorty has suggested that we should better think of philosophy as a literary genre or 'a kind of writing,' as he has put it, held together not by form or matter but by tradition (see Rorty, 1978). While few, for example, would challenge the suggestion that philosophy is about asking critical questions, it makes all the difference whether in asking such questions one takes inspiration from, say, Socrates, Kant, Marx, or Derrida, to name but a few of the critical philosophers. (On the particular issue of what it means to be critical see Biesta and Stams, 2001.) While few would challenge the suggestion that philosophy is about the exploration and exposure of underlying assumptions, it makes all the difference whether in doing so one takes inspiration from, say, Plato, Hume, Hegel, or Foucault. And while few would challenge the idea that philosophers have important things to say about knowledge, belief, and truth, it again makes all the difference whether one does so from the perspective of, say, Aristotle, Descartes, Locke, or Dewey. Philosophy thus presents us with a vast arsenal of ideas, approaches, traditions, and ways of thinking that cover a wide range of areas, including logic, epistemology, ethics, esthetics, metaphysics, anthropology, social and political philosophy, philosophy of language, and philosophy of science. In this way philosophy provides much more than

a huge resource for the study of education and its problems. Many of the topics that have been explored by philosophers throughout the centuries are actually highly relevant for the study of education (see below).

What 'Is' Education?

The word education has Latin roots (a combination of 'ex' and 'ducere') and literally means 'to lead out.' Some have taken this to argue that education not only *is* a process that leads people out of their current beliefs and ways of doing, but also that education *ought to* lead people 'beyond the present and the particular' (Bailey, 1984). When we look at the word 'education' in more detail, we can distinguish at least five different ways in which it is being used. First, it is used to refer to *institutions* such as schools, colleges, and universities. Hence we talk about primary, secondary, further, continuing, and higher education. Secondly, partly related to this, 'education' is used to refer to *domains of practice*, such as adult education, school education, vocational education, technical education, or university education. Thirdly, the word is used to refer to the *processes* that go on in such institutions and practices. Fourthly, the word is used to refer to the *activity of educating*. Teaching is one obvious example of this use of the word, and parenting another. Fifthly, the word is also used to refer to the *outcomes* of education, such as in the idea of the educated person, a topic extensively discussed in the philosophy of education literature (see, e.g., Peters, 1970; Martin, 1981).

While the English word 'education' thus contains multiple meanings, other languages are sometimes slightly more helpful in that they use different words for these different meanings (see also Biesta, 2011). One such distinction can be found in the German language, where the word 'Bildung' is used to refer to processes of education whereas the word 'Erziehung' is more often used to refer to the activity of educating. 'Bildung' (sometimes translated into English as 'formation' or 'edification') refers to the ways in which, through engagement with culture and tradition, we develop our human capacities. It thus comes with an idea of education as cultivation and enculturation and, more importantly, with an explicit idea of what it means to be educated. This obviously means that not *any* engagement with culture and tradition necessarily contributes to the 'Bildung' of a human person, so that one important question with regard to 'Bildung' concerns the selection of those aspects of culture and tradition that are deemed to be beneficial for one's 'Bildung.' The idea of 'Erziehung' is less about processes and more about the activity of educating. 'Erziehung,' therefore, implies intention on the side of the educator (an educator has the explicit intention to have some impact on the one to be educated) and the articulation of what the activity of 'Erziehung' is supposed to bring about, that is, a sense of the aim or aims of 'Erziehung' (see Oelkers, 1993, 2001). Most importantly, 'Erziehung' implies an orientation toward the education of the person as a free human being. This means that the one being educated is never just seen as an object for influence and manipulation but always also as a subject (or an emerging subject) in its own right.

The conceptual complexities surrounding the word 'education' have led several authors to claim that 'education' is an 'essentially contested concept' (Gallie, 1956). The idea of essentially contested concepts in not so much that they are difficult to define or that people have differing opinions about their meaning, but that this difficulty has to do with the fact that such disputes cannot be settled by just referring to 'the facts' or just by means of argument or logic, because the discussion is ultimately not about what the concept means but what it *should* mean. The discussion is, in other words, *normative* and is concerned with people's values and beliefs. We can see this quite clearly in the case of education because on closer inspection many definitions of education are actually statements of what the person defining the concept considers to be *good or worthwhile* education. This is why Richard Peters' definition of education as implying "that *something worthwhileis being or has beenintentionally transmittedin amorally acceptable manner*" (Peters, 1966: p. 25) is not so much a definition as a statement of his views about *good* education. There is actually nothing wrong with the fact that discussions about what education is or ought to be are thoroughly normative and thus always require engagement with questions of values. After all, if we take education in the sense of educating (the fourth meaning) toward becoming an educated person (the fifth meaning), it is always about deliberate attempts to effect change in someone's knowledge, beliefs, values, attitudes, skills, or personhood – which always raises the question of justification, that is, the question to what extent such changes can be considered desirable.

This is a complicated discussion with a long history that became even more complicated as a result of the rise of Enlightenment ideas of human self-determination and freedom. If, to put it briefly, before the Enlightenment the educational keyword was that of 'perfection' – that is, making the human being more perfect through its engagement with the best aspects of culture and tradition – from the Enlightenment onward the educational keyword became that of 'autonomy,' that is, using one's rational capacities for responsible self-determined action. This shift has resulted in what has become known in the literature as the 'educational paradox,' very aptly summarized by Immanuel Kant in the question "How do I cultivate freedom through coercion?"

The Question of Purpose in Education

The normative dimensions of any discussion about education reveal one further characteristic of the concept of 'education,' which is the fact that 'education' is what in the philosophical literature is known as a *teleological* concept; that is, a concept that implies a *telos*, which is, an aim or purpose. The idea here is that education is not an activity we undertake just for its own sake, but always because we want to achieve something or bring something about. Talking about education thus always raises the question as to what education is *for*. There are quite different views about what education should be for, not only depending on people's understandings of what education 'is' but also, and more importantly, depending on the values they hold and the views they have about what education ought to achieve. Viewed from this angle it is actually quite difficult to make any clear statement about what the purpose or purposes of education should be. This does not mean, however, that it is

not possible to bring some more clarity and precision in discussions about the purposes of education.

A first step toward such clarification is to acknowledge that educational systems perform a number of different functions (see Biesta, 2010a). One major function of education – particularly of formal education – is that of *qualification*. This has to do with providing children, young people, and adults with the knowledge, skills, and understandings and often also with the dispositions and forms of judgment that allow them to 'do something' – a 'doing' which can range from the very specific (such as in the case of vocational or professional education) to the much more general (such as the role of education in preparing children and young people for life in highly complex societies). A second major function of education is that of *socialization*, which has to do with the ways in which, through education, we become initiated into and part of existing social, cultural, political, professional, or religious communities, practices, and traditions. In some cases, socialization is actively pursued – for example, where the aim is to inculcate the values of democratic citizenship or the ways of doing and being of particular professional communities. But even if socialization is not an explicit aim of educational programs and practices, education will still have a socializing 'effect' on those who take part in it – a phenomenon well documented in the idea of the 'hidden curriculum.' Through its socializing function education inserts individuals into existing ways of doing and being and thus plays an important role in the continuation of culture and tradition. Education does, however, not only contribute to qualification and socialization but always also impacts on the human person. Here, education performs the function of subjectification, that is, of becoming a subject of action and responsibility rather than remaining an object of the demands and directions of others.

The distinction between qualification, socialization, and subjectification is not only useful in order to get a clearer understanding of the different ways in which education *functions*, but we can also consider them as *three different domains of educational purpose*; that is, three domains we can – and in a sense ought to – take into consideration when we try to articulate what education should be for.

The Encounter between Philosophy and Education: Some 'Classics'

Having started from the simple definition of philosophy of education as the philosophical study of education and its problems, and having tried to give an answer both to the question of what philosophy is and to the question of what education is, we can now see that the encounter between philosophy and education contains a vast array of possibilities, not only because of the variety of philosophical positions, traditions and ideas, but also because of the complexity of the very notion of education itself. What makes this encounter even more rich and complex is the fact that, unlike in the domain of science where new theories and insights tend to replace older ways of thinking, many if not all of the ideas generated by philosophers over the centuries remain valid or at least interesting. This is because in philosophy later views tend not so much to *replace* earlier insights and ideas as that they add depth, detail, complexity, and controversy to the discussion.

When we look at the actual work done in the philosophy of education, two things stand out. One is that throughout the whole history of philosophy, philosophers themselves have been discussing educational issues and in doing so have generated a number of real 'classics.' In Plato's text *The Republic* (Plato, 1955) we can, for example, find a detailed account of the roles of education in the ideal state, with a clear distinction between the kind of education that the guardians of this state should receive and the kind of education that the rulers of the state, the so-called 'philosopher-kings,' should have. Plato not only provides much 'technical' detail but also discusses extensively the aims and methods of such education. Interestingly, Plato connects the education of the rulers of such a society strongly with philosophy – in a sense he proposes a philosophical education for them – highlighting the crucial importance of knowledge of the good. In *The Republic* which, as many of Plato's writings, is written in the form of a dialogue – in this case one in which Socrates is the main protagonist – Plato introduces a number of ideas and metaphors, such as the idea of education as a process of 'turning the soul' toward the light of knowledge, that are still being discussed today (see, e.g., Haroutunian-Gordon, 2010).

It is, however, not only the *content* of Plato's writings that has made a lasting impact on educational thought. Perhaps even more famous and influential is its dialogical *form* which itself can be understood as a particular view of education. Here we often find Socrates, through a refined play of questions and answers, bringing his interlocutors to insights and understandings including, often, an acknowledgment of the limits and limitations of one's own knowledge on the assumption that the first step to wisdom is recognition of one's own ignorance. Socrates often claimed that he actually knew nothing. This approach has become known in the literature as the Socratic method or Socratic teaching and often compares teaching to the practice of midwifery, that is, a process of bringing out what is already inside – that is, a process of helping students to come to clearer insight and understanding – rather than as a process where the teacher would transmit something new to the student. Aspects of the Socratic method can also be found in what is known as Philosophy for Children, an approach to engage children in philosophical enquiry developed by the American philosopher Matthew Lipman (1922–2010) that has become a popular program around the world (see, e.g., Lipman et al., 1980).

Another important and at the time highly influential text on education written by a philosopher is John Locke's *Some thoughts concerning education*, which was published in 1693 (see, e.g., Locke, 2008). In this book Locke presents, among other things, his idea of the mind as a 'tabula rasa,' that is, as a clean slate upon which experience makes impressions, thus highlighting the crucial important of education on the formation of the human being. Locke also highlighted the importance of instilling good habits in children before embarking on more academic and intellectual forms of education, and discussed extensively the formation of virtue and reason, a process that should focus on treating children as rational beings and on using esteem and disgrace rather than rewards and

punishments as the latter would arouse 'passions' rather than reason. That Locke's text was highly popular and potentially highly influential can be seen from the fact that in the eighteenth century alone it was published in at least 53 editions in English, French, Italian, German, Dutch, and Swedish (see Axtell, 1968: pp. 100–104).

The third major work to mention is Jean-Jacques Rousseau's *Émile, or on Education* which was published in 1762 (see, e.g., Rousseau, 1979). The book – which contains the famous opening sentence "Everything is good as it leaves the hands of the author of things, everything degenerates in the hands of man." ("Tout est bien sortant des mains de l'Auteur des choses, tout dégénère entre les mains de l'homme.") – uses the device of a story about the education of the child and young man Émile by his tutor and also contains a (shorter) section on the education of Sophie, Émile's wife-to-be. One aspect of what Rousseau puts forward in the book is the question of how to balance what is 'of the child' with what is 'of society.' In the psychological literature this issue is often discussed as the 'nature-nurture' debate and concerns the question to what extent what we become is the result of internal (nature) factors or the result of external (nurture) factors – nowadays most people would argue that it is an interaction between the two rather than one or the other. The educational question is, however, not about explaining the factors that contribute to what we are or become, but raises the issue how we can, in terms of Rousseau's argument, maintain the original goodness of the human being while at the same time becoming good and responsible members of society. The educational question here, in other words, is about how to deal with the fact that any engagement with education – either through our own enculturation ('Bildung') or through the efforts of others to impact upon our growth ('Erziehung') – is not just a gain but also potentially a loss (for a poignant discussion of this experience see Kerdeman, 1999; also Mollenhauer, 1983).

Another classical text in the philosophy of education is a short publication attributed to Immanuel Kant (though probably authored by someone else based on notes from a lecture) called *On Education* (*Über Pädagogik*), published in 1803 (see Kant, 1803, 1982). In *On Education*, Kant highlights the crucial role of education in helping human beings to develop their rational powers in order to achieve rational autonomy – that is autonomy based on the use of reason. In his short text "An answer to the question: What is Enlightenment?" (originally published in 1784; see Kant, 1992) Kant had defined the 'motto' of Enlightenment as 'sapere aude,' that is, 'dare to think' or have the courage to use your own capacity for reason. What is interesting from an educational perspective is that Kant did not conceive of this capacity as a contingent historical possibility – something that individuals could either acquire or not – but saw it instead as something that was a central part of human nature. He described the "propensity and vocation to free thinking" as man's "ultimate destination" and as the "aim of his existence" (Kant, 1982: p. 701), which meant that to block progress in enlightenment would be "a crime against human nature" (Kant, 1992[1784]: p. 93). Interestingly enough, however, Kant also argued that the 'propensity to free thinking' could *only* be brought about through education (see Kant, 1982: p. 710). Kant not only wrote that man "is the only creature that has to be educated" (Kant, 1982: p. 697), but he also argued that the human being can only become human – that is, a rational autonomous being – "through education" ("Der Mensch kann nur Mensch werden durch Erziehung"; Kant, 1982: p. 699). With Kant the rationale for the educational 'project' became founded on the idea "of a certain kind of subject who has the inherent potential to become self-motivated and self-directing," while the task of education became one of bringing about or releasing this potential "so that subjects become fully autonomous and capable of exercising their individual and intentional agency" (Usher and Edwards, 1994: pp. 24–25).

The fifth 'classic' to be mentioned here (although this list is far from exhaustive) is John Dewey's *Democracy and education*, a book that was first published in 1916 (see, e.g., Dewey, 1966). Although the subtitle of the book is *An Introduction to the Philosophy of Education*, the book does much more than just introducing the philosophy of education. In the context of an impressive account of the development of educational thought throughout the centuries, the book not only provides a detailed account of Dewey's own 'theory of education' – a theory that, looked at from a Continental perspective, is perhaps more a theory of 'Bildung' than a theory of 'Erziehung'' (see also Siljander et al., 2012) – but also includes a statement of his still influential ideas about the relationship between education and democracy (Biesta, 2010b).

There are of course many more books in which philosophers have engaged with educational questions, and one could argue, looking at the history of such publications, that for a long time major thought about education was indeed generated by philosophers. It is important to mention here – although in a sense it is difficult to have missed this in the discussion so far – that the history of philosophy is entirely dominated by men even if, such as in the case of Rousseau, the discussion is about the education of women. Mary Wollstonecraft (1759–97), now considered to be one of the early feminist philosophers, actually wrote a strong critique of Rousseau's ideas in her *A Vindication of the Rights of Women* (published in 1792; see e.g., Wollstonecraft, 2004). It has only been in recent decades, particularly in North America through the work of such authors as Jane Roland Martin (see, e.g., Martin's landmark book *Reclaiming a Conversation: The Ideal of the Educated Woman* from 1985) and Nel Noddings (see e.g., her *Caring: A Feminine Approach to Ethics and Moral Education* from 1984), that feminist thought has begun to influence the philosophical conversation about education (see also Stone, 1994; Weiner, 1994).

The Contemporary 'Field' of Philosophy of Education

While this work draws inspiration from wider developments in feminist philosophy and theory – and while the impact of feminist thought on education has also been achieved through, for example, feminist psychology, sociology, and cultural theory – feminist philosophy of education should be understood in the context of an important development in the second half of the twentieth century, that of the establishment of philosophy of education as an own 'field' or

specialism, institutionally more strongly located in university schools and departments of education than emanating from schools and departments of philosophy. In the first half of the twentieth century, as Phillips (2001) makes clear, philosophy of education existed mainly of what he characterizes as the 'isms' approach, a way of conducting philosophy of education that locates itself within a particular philosophical school, tradition or approach – such as realism, idealism, Thomism, existentialism, or pragmatism – and then asks what the implications for education of taking such a philosophical stance would be. Phillips suggests that the 'isms' approach suffers from two problems, one being the fact that there is no "simple one-to-one correspondence between a person's deep philosophical commitments ... and his or her everyday actions, or actions in the classroom" (Phillips (2001): p. 4290) and the other being that this approach relies on an "oversimple notion of implication" (Phillips, 2001).

The major way in which philosophy of education established itself from the 1950s onward was in the form of *analytic* philosophy of education – sometimes known as 'APE' both by its admirers and its critics. The work of Israel Scheffler in North America and that of Richard Peters and Paul Hirst in the United Kingdom played a major role in the development of analytic philosophy of education as the dominant approach in what it meant to do philosophy of education. Many others followed in their footsteps and it can be argued that up to the late 1970s or early 1980s analytic philosophy of education – which took its philosophical inspiration mainly from philosophy of language, logic, and epistemology – was the dominant approach in the field. Analytic philosophers of education partly focused their efforts on the analysis and clarification of key educational concepts such as 'teaching' (see, e.g., the discussion of Peters' analysis of the concept in chapter 1; or Macmillan and Nelson, 1968) and 'learning' (see, e.g., Phillips and Soltis, 1985), or of the wider language of education (see, e.g., Scheffler, 1980; see also Peters, 1966; Dearden et al., 1972). In addition to the analysis of key educational concepts (see also Soltis, 1968), the analytic philosophers of education were also interested in exploring the nature of knowledge, truth, and rationality, which resulted in a strong interest within analytic philosophy of education in questions of critical thinking and its education (see, e.g., Siegel, 1988 and, for a critique and reformulation inspired by feminism and pragmatism, Thayer-Bacon, 2000). (For an intriguing and highly readable account of the history of analytic philosophy through a number of intellectual 'self-portraits' see Waks, 2008.)

From the 1980s onward, philosophy of education has become increasingly diverse and plural, engaging not only with a much wider array of philosophical ideas and fields – including social and political philosophy, ethics and moral philosophy, and esthetics – but also with a much wider range of philosophical traditions – including feminist philosophy, postmodern and post-structural philosophy, critical theory, and increasingly also with Aristotelian thought (for an early overview see Kohli, 1995). Another important line within philosophy of education was the rediscovery of pragmatism as a philosophy and a philosophy of education (e.g., Garrison, 1995). While in some regard the range of topics and issues that philosophers of education focus on has expanded together with the widening of philosophical orientations from which the field draws, there is also clear evidence of a return of the 'isms' approach, as many publications focus either on the educational implications of particular philosophical schools and traditions – such as pragmatism, postmodernism, and post-structuralism – or of particular philosophers. The proliferation of philosophical and theoretical orientations within contemporary philosophy of education has, on the one hand, raised questions about what the specific identity of philosophy of education (still) is, but has, on the other hand, opened up new alliances and opportunities, particularly with those who, while working in such fields as curriculum theory and cultural studies of education, draw inspiration from similar philosophical and theoretical resources. While some have expressed concerns about the relatively marginal status of philosophy of education within the wider field of educational research and scholarship, some of the key international journals in the field of philosophy of education – such as *Studies in Philosophy and Education*, *Educational Philosophy and Theory*, *Educational Theory*, and *The Journal of Philosophy of Education* – not only show the high level of activity within the international (English-speaking) philosophy of education community but also provide evidence of the still growing interest in the writings of philosophers of education.

Concluding Comments

Philosophers have always had an interest in educational questions and in this regard philosophy of education can be considered to be as old as philosophy itself. As a distinct field or specialism within educational research and scholarship philosophy of education emerged in the twentieth century and gained its identity perhaps first and foremost through the rise of analytic philosophy of education from the early 1950s onward. More recently, the field of philosophy of education has become more diverse and plural, drawing from a wide range of philosophical traditions and engaging with an equally wide range of educational topics and concerns (for a recent example see Biesta, 2012). One question that remains unresolved with the field of philosophy of education is whether philosophy of education should be understood as a form of applied philosophy that has its intellectual and disciplinary 'roots' within the field of philosophy, or whether it is a form of educational scholarship that draws inspiration from philosophy. Finally, it is important not to forget that the very idea of philosophy of education emerged in the English-speaking world and is therefore closely connected to how the field of educational scholarship has developed more generally in this context, namely in the form of the inter- or multidisciplinary study of education rather than as an academic discipline in its own right. It is, therefore, important not to assume that philosophy of education is a universal phenomenon that has its equivalent in all countries and languages. There remain important and significant differences between how more theoretical and philosophical dimensions of the study of education have gained shape and form in different contexts (see Biesta, 2011), and the idea of philosophy of education is

just one approach within a wider array of ways of engaging theoretically and philosophically with education.

Educational Planning Worldwide

Françoise Caillods, Formally Deputy Director of the International Institute for Educational Planning, Currently Senior Advisor at the International Social Science Council, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by J. Hallak, volume 6, pp. 4292–4296, © 2001, Elsevier Ltd.

Abstract

Educational planning is the activity that allows the public authorities to orient educational development and identify priority interventions. After going through a major crisis of confidence in the 1980s, educational planning has undergone major transformation: it has become more participatory, more flexible, less technocratic, and more diverse. It has gone beyond what its main focus was for a long time – planning infrastructures, increasing access, and increased efficiency – to become more strategic and addressing a variety of key issues of the educational system, such as quality, inequality, and factors influencing demand for schooling.

Educational planning is the activity which allows the public authorities to orient educational development, set priorities in consultation with other actors, identify priority interventions, and extend funding support to achieve the country's economic and social objectives. It is about exploring the future and developing a vision of what the education system should look like in the next 5–10 years, and identifying what needs to be done to reach this desirable situation.

Educational planning involves a series of steps: analyzing the conditions of the educational system at base year, identifying its major strengths but also its problems and constraints, projecting enrollment on the basis of objectives set by the policy makers, identifying possible strategies to address problems identified, and projecting the necessary human and financial resources required to reach the desirable situation at a reasonable cost. After going through a major crisis of confidence in the late 1970s and 1980s, educational planning has undergone major transformation: it has become more participatory, more flexible, less technocratic, and more diverse. It has gone beyond what its main focus was for a long time – planning infrastructures, increasing access, and increased efficiency – to become more strategic and addressing a variety of key issues of the educational system, such as quality, inequality, and factors influencing demand for schooling. Educational planning is no longer practiced in the planning unit of the Ministry of Education only: it is practiced at all levels from the central to regional level down to the institution and school level. We shall first review what educational planning was early on when it became a major activity of ministries of education, the reasons why it was criticized, the factors that contributed to shaping the way it is now, and the way it is practiced now in a range of countries.

A Bit of History

Socialist states have prepared directive plans ever since the Soviet revolution in 1917. After World War II nonsocialist countries in Europe such as France and the Netherlands also prepared plans to guide their postwar recovery. Japan and the Republic of Korea did the same. But it is in the developing countries that most educational planning activities took place. After independence, in the 1950s and 1960s, numerous countries engaged in rapid expansion of their education system with a view to educating their population and fostering economic development. Several countries had the ambition to universalize access to primary education following the various regional conferences sponsored by UNESCO in Karachi in 1960, Addis Ababa in 1961 and Santiago in 1962. The greatest constraints to development were nevertheless perceived as being the lack of skilled manpower: engineers, doctors, and managers. Most countries created an educational planning unit within their ministry, which were entrusted with the task to estimate their economy's skilled manpower requirement and plan the physical, financial, and human resources needed to support the expansion of the system.

The human capital theory, which was developed in the 1960s, established a link – presented as causal – between years of education, knowledge and skills, productivity, higher earnings, reduced inequality, and faster economic growth. By increasing the people's productive capacity, education was meant to help increase national production and the country's future wealth, while at the same time providing other benefits such as reduced fertility, better health, and nutrition (Schultz, 1961). This theory provided a powerful – albeit often criticized – framework for making choices between investment options (Blaug, 1976). It was used to justify the huge investment made in education both in developing and developed countries. Theoretical discussions concerned the criteria that should guide the development of education at postprimary level. Bid debates existed among economists of education concerning whether planners should use the manpower planning approach (that explicitly gears the degree and type of educational expansion to the anticipated demand for different categories of labor), the investment approach (linking the rate of expansion of one educational level to the rate of return of investments made at different levels), or the social demand approach (essentially projecting past trends). According to the approach followed, more priority was given – or not – to specialized education (technical and vocational education; higher education). Debates continued for many years but on the whole, the three approaches led to the rapid expansion of education (Bertrand, 2004).

Thirty years later, the great hopes that were placed in education and in educational planning were seriously shaken (Caillods, 1989). The economic crisis of the 1970s and 1980s led to rising unemployment among graduates; poverty and

income inequalities within and between countries had not disappeared, on the contrary; as more and more credentials were required to have access to the same jobs, the idea emerged that education could be nothing else but a screening device to select best candidates, without necessarily contributing to productivity. These developments shed doubts on the fact that education did drive economic growth.

With the introduction of structural adjustment programs in several countries, many plans did not get implemented. A number of recommendations were made which came to be known as the Washington consensus (promoted by big international organizations such as the World Bank, the IMF, and the US treasury department all based in Washington) which emphasized cutting on government expenditures and relying more on market forces in education provision and elsewhere in the economy. Planning lost much of its prestige. Several countries stopped preparing plans. These were replaced by policy analysis and a multiplication of projects financed by different donors, largely uncoordinated (Caillods, 1989).

The combination of the economic crisis, the cutting of government expenditures, and the lack of appropriate planning eventually led to a serious deterioration of the education coverage and quality in developing countries, even in a region where education was quite advanced as Latin America. This is why UNESCO, UNICEF, the World Bank, and UNFPA decided to convene the World Conference on Education for All (EFA), which took place in Jomtien, in 1990. The World Declaration on EFA was then adopted, which stressed that education is a fundamental human right and pushed countries to strengthen their efforts to improve education and meet the basic learning needs for all. The international community met again 10 years later at the World Education Forum in Dakar and the participants reaffirmed their commitment to achieving EFA by the year 2015 (UNESCO, 2000).

These two events put educational planning back on the agenda. But planning as it became practiced was quite different from what it used to be.

Traditional planning has been replaced by strategic planning, which involves a variety of different plans from long-term plans to medium-term plans, 3-year operational plans, and 1-year plans, linked to the preparation of the budget. Planning is no longer a one-shot operation leading to the preparation of a document which remains on a shelf: it is now a continuous cyclical process that includes different phases from diagnosis, policy formulation, plan preparation, and costing to plan implementation, monitoring, and evaluation. The implementation stage, and the design of appropriate programs and projects, is part and parcel of the planning process. Also planning is no longer a technocratic exercise prepared by a small group of experts: it involves a large number of actors at central, regional, and local levels.

From Traditional Planning to Strategic Planning

1. Several factors contributed to shaping educational planning as it is practiced now in many developing countries (Caillods, 1997; UNESCO PROAP, 2005; Carron et al., 2010):
   a. To start with the international commitment in favor of EFA. Numerous commitments were made by national governments in the 1990s and 2000s which engaged all governments, those in developing and donor countries (UNESCO, 2000). The commitment in favor of EFA was shortly afterward followed by another international commitment in favor of poverty reduction (the Millennium Development Goals). These two international commitments influenced national policy choices in favor of primary and basic education, girls' education, and to a lesser extent preschool, literacy, and nonformal education. They also influenced donor agencies who gradually shifted their development assistance away from support for higher skill development programs in favor of basic education. It finally strongly emphasized planning: every country had to prepare a national EFA plan, in order to get external funds.
   b. Changes in the practices of external agencies. The concern of development partners for a proper implementation of the EFA goals has had the effect of putting planning back on stage. The existence of a 'credible plan' in favor of basic education became a precondition for external financing. New aid practices emphasize the leadership of the host country, and the existence of locally owned programs of development. Consultation of local stakeholders was taken as an indicator of the country's commitment and a possible guarantee for its successful implementation. New aid modalities increasingly included sector-wide approaches and budget support (sector or full budget support) in the framework of which the resources of several development partners are coordinated. In such schemes, funds are provided to the Ministry of Finance on the basis of an approved sector policy document, with an agreed strategic framework which specifies clear measurable outcomes to be attained within a given time frame. These become the year by year milestones against which progress is measured and funding tranches are released. Access to other international funding schemes (such as the Global Partnership for Education, formally called the EFA Fast Track Initiative) and possibility of debt relief also required that heavily indebted low-income countries prepare a country-driven and -owned Poverty Reduction Strategy Paper, which is based on long-term perspectives and broad consultation of the civil society (Caillods and Hallak, 2004).
   c. Decentralization: As systems of education expanded, it became less and less feasible for central governments to administer education directly. Decentralization of responsibilities to a lower level of governments occurred in every sector as an attempt to improve the efficiency in state governance. In education, the decentralization process often started as a way of tackling the financial crisis passing the burden of financing primary and secondary education to local authorities. It has also been a way of correcting the inefficiency of central administration, placing the locus of decision-making closer to where action is really taking place. The decentralization process took many forms transferring authority to lower administrative levels (deconcentration), to elected bodies accountable to local population (decentralization), or to the private sectors (Mc Ginn and Welsh, 2000). In many countries of South East Asia and Latin America, provincial or state education authorities have thus been entrusted with new

responsibilities in terms of allocation and utilization of resources. Yet the decentralization process is not devoid of problems as richer provinces/states and communities, having more resources and more capacities, often develop faster than others. Central planning remains nevertheless essential to ensure coherence between the different regional plans, to train and support staff in all provinces, to monitor regional developments, to assign resources according to different criteria, and to propose measures to reduce disparities.

d. Modernization of public sector management (UNESCO PROAP, 2005).
Education is the largest public sector in many countries. It is therefore directly affected by public service reforms. It is also often chosen as a pilot sector for such reforms. Decentralization just described is the first type of reform in public sector management which affected education, but also other sectors. Other reforms concern budget management. No plan, no project can be implemented unless it is duly taken into consideration in the national budget. Ministries of finance have started preparing a 3-year budget so as to be able to anticipate what the longer-term impact of various sector policies is and check that they will have the necessary resources to finance them. This reform started in developed countries and spread to developing countries. Increasingly multi-annual budgets, called medium-term expenditure frameworks (MTEFs), get prepared. They are meant to increase the predictability of the budget planning process by providing more reliable estimates of expenses and revenues over a 3-year-period. It is based on the various 3-year plans prepared by different ministries. The better the sectorial plan the more likely it is that it will be properly reflected in the MTEF. Finally, the modernization of public sector management influenced planning by promoting result-based management. What is to be monitored is not so much whether activities have taken place as planned but that expected results and outcomes have been reached.

e. A final factor which influenced planning practices is the spreading of new information technologies and availability of cheap and powerful computers. Preparing a plan, estimating enrollment, and assessing resources requirement used to take ages 30 years ago and limited the number of options that could be analyzed. The new information technology made it very easy to analyze a large number of data and develop simulation models, and to test various hypotheses. Several models exist which allow one to prepare various scenarios of enrollment expansion and costing them. These facilitate the policy dialogue and the presentation of various options to different audiences of stakeholders.

2. Characteristics of strategic planning or modern educational planning.

Several critiques were addressed to the old model of educational planning in the 1980s and 1990s (Hallak, 1997; Carron et al., 2010). According to these, educational planning, as it was practiced in many developing countries, failed primarily because it was too technocratic, too much conceived as a top-down exercise (thus not allowing to build ownership), too rigid (unable to adapt to changing circumstances), too focused on investments and infrastructures and not enough on quality of learning, and not paying attention enough to implementation (such as linking planning with budget preparation for example).

Strategic planning – a concept which was elaborated for the business sector – was widely adopted in education as a reaction to the above criticisms (Caillods, 1989, 1997; Carron et al., 2010). By contrast to what was occurring before, strategic planning:

a. Is guided by a vision of where the country wants to go, what it wants to achieve in the long term, and how this translates into major political orientations for the educational system. The vision and the long-term goals are meant to mobilize the efforts of the various actors and make sure that this is the direction they will all strive for.

b. Is built on knowledge: strengthening of the educational management information system, analysis of indicators, conduct of surveys, review of existing research on key educational issues, evaluations, wide consultations of stakeholders to ascertain what the main strengths and problems of the educational systems are, what the main constraints and blockage in the implementation of previous policies were; what do the stakeholders – families, students, employers – expect from the educational system; and which strategies are most likely to address the problems encountered.

c. Is sensitive to the environment and starts with a thorough analysis of the context: demographic, sociocultural, economic, and political. It is aware of possible risks and tries to adapt to new situations as they emerge, not losing sight of the results the countries want to achieve.

d. Is flexible in its implementation. A strategic plan defines clearly what its final goals and expected outcomes are and which strategies will be used to get there but it does not enter into the details of the different activities and steps to be followed. The identification of major programs and projects, and plan monitoring are integral parts of the planning process, allowing changes to be introduced if the implementation of a certain strategy does not lead to expected results.

e. Recognizes that educational change is the sum of thousands of microdecisions. What explains the success or the failures of a policy may not necessarily be attributed to one particular intervention but to the demand and perception of many independent actors making decisions. It is therefore essential to identify who the different actors are and what is likely to influence their actions and decisions (Kemmerer and Windham, 1997). Stakeholder analysis is a common feature of many educational plans.

The Practice of Educational Planning Today

The situation is different in aid-supported countries and in middle-income countries. Advanced countries no longer practice educational planning at the central level but some of them continue to develop a long-term vision, identify priority programs in the framework of the preparation and implementation of an overall reform, and widely consult stakeholders. Planning is more practiced at the decentralized level and at the institutional levels (universities and schools).

1. Strategic and operational planning in aid-supported countries.

Most countries that are dependent on external assistance have developed a medium-term plan, based on a long-term vision. These plans pretty much follow the same approach. They start with a situation analysis at base year reviewing for the different educational levels performance in terms of access, equity, and quality improvement. On the basis of such diagnosis and of evaluation of the implementation of past policies they define the overall development objectives of the plan and its specific objectives. The list of priority programs and projects that will lead to expected outcomes is then given. The resource implications of the plan are measured with the help of a simulation model, and the possible financing gap assessed. The objectives, the expected outcomes, and output with specific targets are presented in a logical framework. (Several aid agencies (e.g., USAID, World Bank, EU) have adopted the logical framework approach (logframe) as the core technique for managing the complete project cycle from design to implementation, monitoring, and evaluation. Models of logframes can be found on their respective Web sites.) These are monitored by a set of indicators, which, if the country is on track, act as a trigger for the funds to be released. The last part of the plan is the presentation of the monitoring schemes.

Some plans cover the whole education system from primary to higher education; others cover basic education only from preschool to secondary education. Separate plans are sometimes prepared for higher education or for technical and vocational education. Aid-dependent countries have therefore moved from a situation where planning was largely discredited to one where many plans are prepared (long term, medium term, and short term) and planning has become a high-stake process, which determines the funds they receive from development partners.

Planning has become more sophisticated thanks to the use of the latest technology. The planning process has also become more participatory with more and more stakeholders being consulted including the development partners. The implementation is ensured by the preparation of the programs and projects, which are closely monitored. Programs and projects generally concern increased access and equity (with measures which address both supply and demand for education), improvement of the quality of education (reforms of curriculum and pedagogical approaches, teacher training, teaching materials, and use of new technologies), administration, and governance (improvement of management information systems, recruitment and deployment practices of teachers, financial management, and transparency). (The various EFA monitoring reports give a fair summary of the various complex issues which are on the educational planners agenda (UNESCO, 2005, 2009).)

Closer links are established with the budget preparation, which is facilitating implementation. The medium-term plan is linked to the medium-term expenditure framework, while yearly operational plans are prepared, which outlines the detailed activities to be carried out and which are linked to the yearly budget. When readjustments to the medium-term plan are needed, they are introduced in the annual operational plan.

Medium-term plans and yearly operational plans are being increasingly prepared at regional levels. Various educational institutions also prepare plans: universities, technical institutions, research institutions, examination boards, and schools.

Eventually, the planning unit at the Ministry of Education will become less involved in plan preparation and spend more time coordinating the work of other directorates in the Ministry of Education, launching research, organizing the policy dialogue with national stakeholders and with development partners, advising the ministerial authorities on different policy options to solve particular issues, etc., as is the case in several middle-income countries. Many of them already do it.

2. Planning education in middle-income countries and emerging economies.

The situation is much more diverse in middle-income countries and the kind of planning that takes place may be quite different from one country to the next, and from one region to the next; it also varies with time. In Latin America, a region which has a long tradition in educational planning, planning activities have developed in the past 10–15 years inside and outside the Ministry of Education, at central, regional, and institutional levels. Countries have considerably increased the number of plans which they prepare. Different departments or institutions within the Ministry of Education develop their own plans. Planning activities have been decentralized to lower levels and provinces/regions/states increasingly prepare their own plan, as do the educational institutions. As a result, central educational planners get more time to engage in a policy dialogue with different stakeholders; they advise ministry officials on how to address the continuously burning issues of improving quality, reducing inequalities, and preparing the necessary workforce to remain competitive in an increasingly competitive world. They also advise on the preparation of educational reforms.

One of the main tasks of the planning unit in many countries is to organize a strong management information system to inform decision-makers at different levels and also actors and users of the education systems. The planning unit is in charge of producing reliable and timely educational statistics; relevant and up-to-date indicators; organize surveys on a regular basis such as standardized evaluations of students' achievements; evaluate plans and programs; and commission studies on key policy issues. Planning units have to play the role of a knowledge broker facilitating the multiway exchange of information between knowledge producers and those who use knowledge, such as policy makers, teachers, headteachers, or the general public (Poggi, 2013).

In so doing, educational planners become actors in the process of educational change. They no longer are simple technicians; they assume a political role. This is not new: this was always the case for top educational planners.

Conclusions

We are approaching the year 2015, the date fixed for reaching the Dakar goals for EFA. Clearly not all countries will reach all objectives. And a good number of primary school age children are still out of school: 61 million according to the 2012 EFA Global

Monitoring Report (UNESCO, 2012). Getting the last 10% in school will require a lot of effort and innovative approaches. Yet a good number of countries have significantly increased their net enrollment ratios at the primary level. This is largely due to the mobilization of the international community, the introduction of effective policy measures (such as free primary education, conditional cash transfers, crash programs for training, and recruiting teachers), and effective educational planning.

What will happen to educational planning when there is no need for building a large number of new schools, for training a large number of new teachers etc.? The experience of middle-income countries shows that there is still a lot to do for educational planning. New challenges have emerged such as preparing countries to enter the new knowledge economy, and promoting innovation and knowledge-based processes in an increasingly competitive and market-oriented environment. This brings back to the fore the need to invest in technical and vocational education and in higher education in addition to focusing on quality and training at the primary and secondary level (Hanushek and Wössman, 2007). Planning will no longer be the exclusive responsibility of one unit or directorate in the Ministry of Education, nor will it be the responsibility of the Education Ministry alone. There are a host of other actors that need to be engaged from trade unions to universities, companies, and businesses. Ministries of education will remain responsible for ensuring high-quality, efficient, equitable, and innovative education. More than ever planning units will have to monitor educational developments paying particular attention to equity and to learning achievements. They will increasingly have to focus on the design of new governance mechanisms based on incentives so as to promote desired behavior of key actors (Kemmerer and Windham, 1997).

Abstract

Key factors that shape development of education policy include actors located inside and outside of government, ideas and values, institutions, and information. Education policy materializes in part when policymakers are persuaded to accept a particular definition of a problem and respond with an authoritative decision such as a law, regulation, rule, or order. Education policy is also shaped by dynamics that occur during implementation. Contemporary education policy is developed in a context of global economic competition.

Education politics consists of a struggle among competing actors to secure government policies that reflect their respective values. Education policy materializes in part when policymakers are persuaded to accept a particular definition of a problem and respond with an official decision such as a law, regulation, rule, or order. Education policy is also shaped by dynamics that occur during implementation. Technical and political factors impact the extent to which policy implementation is faithful to the policy as designed. When government chooses not to respond to claims that an education problem exists, this inaction may be viewed as implicit policy. This article discusses key aspects of the education policy process including actors located inside and outside of government, ideas and values, institutions, and information.

Context, Purposes, and Values

Education has numerous consequences for individuals and societies. Education policy is linked to economic growth, social cohesion, democracy, and the overall well-being of individuals and communities. Education is viewed by many as a fundamental human right essential for the exercise of other human rights (UNESCO, 2013). The World Bank (2014) asserts: "Education is a powerful driver of development and one of the strongest instruments for reducing poverty and improving health, gender equality, peace, and stability."

The historical, economic, social, cultural, and governance contexts of a jurisdiction influence education policy. Education policy in a community with a relatively wealthy, homogenous population that has historically favored government activism is likely to differ from policy in an economically depressed community where the native language of many students differs from the dominant language and there is a history of government distrust.

Education policy is increasingly developed in a global context. Factors contributing to this trend include links between education and economic competition in the global economy, the power of ideas, and the sophistication and speed of modern technologies of information gathering and dissemination. Government officials around the world speak about education in terms of economic strength and competitiveness. The President of the United States Barack Obama declared "countries that out-educate us today will out-compete us tomorrow" (Obama, 2010: 1).

The development of education policy is contentious partly because interests disagree about the purposes of education. There are political tensions between interests who value broad, liberal arts education and interests who favor education policy that emphasizes narrower, technical training closely aligned with labor market needs. Some interests view education largely in terms of workforce development, ensuring jobs for individuals, and advancing collective prosperity. Others favor broader purposes including developing students as well-rounded citizens who think critically and are prepared and motivated to contribute to civil society and democracy.

Some interests portray schools as settings for solutions to social problems. They urge policymakers to require schools to address matters such as childhood obesity, teen pregnancy, drug abuse, and bullying and violence. Debates about curriculum policy extend beyond concerns that students master core academic skills. Interests disagree on the values, norms, and historical events to be included in official curricula (Ravitch, 2004).

Education policy development typically emphasizes one or more of the following values: excellence, equity, efficiency, and freedom. Excellence is often discussed in terms of policies intended to ensure a high-quality education for students. Policies focused on excellence address matters such as curriculum standards and teacher quality. Advocates concerned about equity avow that all students are entitled to a high-quality education. Debates about equity often focus on the allocation of financial and human resources to schools and students. Efficiency refers to whether an education policy yields optimal results from the resources invested in the policy. Freedom refers to elements of autonomy and choice on the part of education producers and consumers. Advocates of deregulation in education are concerned about freedom.

Communities disagree on how these values should be embodied in education policy. Education policy is shaped by how policymakers prioritize and weigh trade-offs among the values. For example, while class size reduction may enable teachers to provide higher quality education to each individual student, delivering education to larger classes is more efficient.

Moreover, there may be policies other than class size reduction that balance preferences for both excellence and efficiency and yield more favorable outcomes.

Governance

The governance system of a jurisdiction refers to the institutions and actors that have authority and power to adopt policies. Education policy is developed within classrooms, schools, subnational governments, and national governments. These institutions may be influenced by ideas and policies developed by international institutions such as the Organisation for Economic Co-operation and Development (OECD), United Nations (UN), and World Bank.

The greater the number of government layers and actors involved, the more complex the education policy process. Government complexity can inhibit citizen participation in education policy as it can be difficult to sort out the institutions, policies, and actors that are responsible for particular outcomes. Thus, government complexity inhibits accountability in education policy. On the other hand, multilayered governance offers multiple options for securing policy change (Baumgartner and Jones, 1993).

There is not consensus among education policy researchers, politicians, and stakeholders regarding optimal forms of education governance. Participants in education policy networks debate the merits of centralization versus decentralization and democratic control versus privatization. The public benefits of education justify public funding (Friedman, 1962). Privatization advocates such as Milton Friedman emphasize the freedom value. They prefer that schools be publicly funded yet operated by nongovernment actors free from democratic control and most government regulations (Chubb and Moe, 1990).

There is a lack of research evidence regarding whether particular forms of education governance yield better student outcomes than others (Manna and McGuinn, 2013). Given that student outcomes are determined by a multitude of in-school and out-of-school factors it is difficult to isolate the independent impact of governance. In some cases, the objectives of an education policy are defined by a central government and the means by which to achieve the objectives are decided by decentralized institutions. This blend of centralized and decentralized policymaking permits adaptation of policy to local conditions and local innovations that can inform future centralized policymaking.

In systems of federalism, it is useful to distinguish between federal education policy imposed by the federal government and national education policy that results from subnational units independently adopting similar policies. Canada is unusual among industrialized federations because it does not have a federal department of education and it has relatively few federal education policies. The provinces and territories have adopted many similar education policies and education equity and student outcomes in Canada rank well internationally. Subnational governments are motivated to develop and adopt national education policy due to global economic competition, pressure for subnational units to rank well against each other, policy learning, the power of policy ideas based on logic rather than partisan calculations, and efficiency concerns (Vergari, 2010).

Education Policy Actors

Actors engaged in the education policy process can be classified according to their location inside or outside of government, whether they hold their positions due to election or appointment, and the extent to which they are visible. Visible actors often fulfill prominent roles in placing problems on the policy agenda while less visible and hidden actors are typically more involved in developing proposed policy solutions for problems (Kingdon, 2011).

Government actors include elected and appointed officials and civil servants at the national and subnational levels. Nongovernmental actors include political parties, interest groups, foundations and think tanks, and the mass media. Some of the most active interests in education politics include teachers, business, and foundations. Parents are key stakeholders in education but are not well organized for sustained, broad involvement in education policy. A threat of a school closure or a proposal to cancel a beloved school sports program can mobilize parents for temporary engagement in the education policy process. Once such issues are resolved, parent involvement in policy typically recedes. While schools exist to serve students and prepare them for life in their communities, their voices and potential roles of students in school systems are widely neglected in education policy (Mitra, 2009).

Philanthropic foundations are located outside of government and, thus, lack authority to adopt government policy. However, foundations can wield significant influence and power over education policy. Foundations distribute private funds to encourage government actors to support foundation policy agendas. Contemporary foundations have engaged in two key strategies. First, they provide direct financial support to initiatives such as school choice and online education in order to help ensure project success. Second, foundations fund information dissemination and policy advocacy. In both strategies, foundation funding is a mechanism for persuading policymakers to allocate public funds in accordance with foundation agendas.

Many foundation leaders have backgrounds in the business sector and promote policies that incorporate business practices in public education. In the United States, the Bill & Melinda Gates Foundation, Eli and Edythe Broad Foundation, and the Walton Family Foundation are prominent actors in the education policy arena. Sometimes called 'the Big Three,' their education reform activism is welcomed by some interests and opposed by others. The Big Three favor market-based approaches in education policy including school choice, competition, deregulation, and merit pay for teachers.

Voluntary state applications to the federal 'Race to the Top' competitive grant program in the United States offer recent evidence that states will change their education policies in order to win federal government funds. Just as jurisdictions typically do not want to forego public funds, they may also be willing to align their policies with the priorities of private foundations in return for foundation grants. Opponents of Race to the Top can participate in democratic processes for

holding the federal and state governments accountable. However, as private institutions, foundations are not subject to the accountability mechanisms of publicly funded, democratic government institutions. Critics concerned about the influence of private foundations assert that foundations are able to shape education policy development free from public accountability (Ravitch, 2010).

Some analysts argue that top-down foundation efforts to develop education policy are less likely to take hold and endure than policies developed at the grassroots level (Reckhow, 2013). When stakeholders participate actively in policy development, as opposed to having policy developed externally and imposed upon them, they are more like to view the policy as legitimate, develop a sense of ownership and commitment to robust implementation, and act to protect the policy from threats over the long-term.

Another type of education policy actor is the policy entrepreneur. Located inside or outside of government, the policy entrepreneur is energetic and persistent in advocating a particular idea or policy. Policy entrepreneurs invest time, energy, reputation, and money in pursuit of their policy objectives. They have a claim to a hearing based on their expertise or leadership position. Policy entrepreneurs are politically savvy and skilled at networking and negotiating (Kingdon, 2011). Education policy entrepreneurs have been successful in promoting market-based policy ideas such as school choice (Mintrom, 2000).

In recent years, there has been an increase in the activities of international and transnational actors attempting to influence education policy development around the world. International actors are intergovernmental entities such the OECD, UN, and World Bank. Transnational actors are nongovernmental entities that operate internationally including philanthropic foundations (e.g., Bill & Melinda Gates Foundation, Open Society Foundations), advocacy networks (e.g., Global Campaign for Education), and businesses (e.g., Hewlett Packard).

Some analysts observe that OECD transitioned rapidly from a forum for information dissemination and learning to an international policy actor purposefully engaged in judging school systems and advising education policymakers. Critical observers have raised questions about OECD influence on global education policy development and the willingness of governments to develop education policy in accordance with OECD values and priorities (Meyer and Benavot, 2013). Similar to philanthropic foundations, OECD is not accountable to voting publics. The precise roles of international and transnational actors – including when, where, and why they are able to influence specific education policies – merit greater attention from the education research community (Mundy and Ghali, 2009).

Problem Definition and Agenda Setting

Persuasion is a key mechanism in the education policy process. In order for an education issue to gain agenda status, policymakers must be convinced that the issue reflects not merely a condition but rather a public problem that merits a government response. Values, interest groups, and information shape problem definition (Rochefort and Cobb, 1994). Policy entrepreneurs and other interests make frequent use of education, economic, and social indicators to persuade policymakers to accept their claims about an education problem. Examples of such indicators include data on graduation rates, poverty, and school funding. Indicators do not speak for themselves and education policy activists are strategic in how they interpret and use indicators. Activists advancing claims about a particular problem often use comparisons and rankings as persuasive mechanisms. Among the most frequently referenced indicators in education policy debates are student scores on standardized assessments.

Interests disagree on whether policymakers should address education problems with policies focused on what happens in schools or with policies that address out-of-school factors. There is widespread agreement that the most important in-school factor shaping student performance is teacher quality. Student outcomes are also determined by many additional factors. A few examples include the quality of the curriculum and instructional tools (e.g., texts, computer technology, and science laboratories), student will and capacity to learn, and infrastructure matters such as optimal seating, lighting, and air quality.

The famous 'Coleman Report' established the significant impact of home, neighborhood, and peer environment on student performance (Coleman et al., 1966). Students may be distracted by concerns about being victims of crime on the way to and from school. They may arrive at school hungry and with untreated health problems, in clothing that is unclean or inadequate for seasonal conditions, and they may be suffering from unstable and troubled home situations. Each of these out-of-school factors impact student readiness and ability to learn while in school.

Comparisons

Problem definition often involves comparisons of policies and outcomes within or across nations (Kingdon, 2011). Advocates of school finance reform point to funding disparities in education and appeal to policymakers by emphasizing values of equity, efficiency, and excellence. Student scores on standardized assessments compose one of the most common, prominent items of comparison in education policy development. Education analysts in the United States compare state rankings on the National Assessment of Educational Progress, a standardized student testing system sponsored by the federal government. In Canada, education analysts rank provinces and territories according to student performance on the Pan-Canadian Assessment Program, a voluntary effort of the provinces and territories coordinated by the Council of Ministers of Education, Canada.

Every 3 years, the OECD administers the Program for International Student Assessment (PISA) to 15-year-olds in participating countries and subnational jurisdictions. The assessment measures reading, math, and science knowledge and skills. First administered in 2000, PISA enjoys credibility among many in the mass media and education policy arena. Indeed, PISA is now a prominent indicator in education policy discourse around the globe. Some interest groups and members of the research community view PISA as a useful mechanism for the development of evidence-based education

policy. Other analysts question the validity and reliability of PISA (Meyer and Benavot, 2013). Two other international assessments in which many nations participate are the Progress in International Reading Literacy Study and Trends in International Mathematics and Science Study, both sponsored by the International Association for the Evaluation of Educational Achievement.

The OECD compares PISA results across countries with very different populations, histories, cultures, values, governance structures, and education systems. Based on its high ranking in several administrations of PISA, Finland became a global symbol of educational excellence and the envy of education policymakers in countries ranking lower on PISA. Critics questioned the usefulness of comparing PISA results of the large, diverse United States with those of Finland, a small country with a much more homogeneous population. Given its subsequent decline on the 2012 administration of PISA, Finland may become a symbol of imperfect global assessments and rankings and the international quest for simple answers to complex problems in education policy.

Dramatic Cases and Crisis Rhetoric

Education activists also use dramatic focusing events, symbols, and crisis rhetoric to convince policymakers that an education problem exists (Kingdon, 2011). For example, policy entrepreneurs refer to school shootings as evidence of problems with school safety or to student suicides as evidence of problems with school mental health services or inadequate attention to bullying prevention. After the Soviet Union became the first country to launch a satellite into space in 1957, 'Sputnik' was a focusing event for education policy development in the United States. In 1958, the federal government adopted the National Defense Education Act to improve science, math, and foreign language training with the aim of competing with the Soviet Union in science and technology fields.

In 2000, member countries of the UN endorsed eight 'Millennium Development Goals' to be achieved by 2015. These goals include achieving universal primary education and promoting gender equality. According to UNESCO (2013), despite increased access to education, up to 250 million children have weak literacy and numeracy skills and 775 million adults lack basic literacy skills. Based on these and other indicators, UNESCO asserted that there is a 'global learning crisis' and called for increased global attention to student access to high-quality learning.

Education Policy Design

Prior to the time that a problem gains status on the government agenda, policy specialists have been working on proposed policy solutions. Brand new ideas do not typically receive substantial attention during the policy design process. Instead, policy designers usually combine elements of prior, familiar options into a new policy proposal (Kingdon, 2011). Policy design is shaped by the power of ideas and interests. Education policy designers consider policy goals and the target population, policy instruments, and implementation arrangements.

Policy proposals must be technically feasible and acceptable on value grounds in order to succeed. Technical feasibility refers to logistics including funding. For example, a viable proposal to introduce year-round public schooling in a community would address technical issues such as funding, scheduling, curriculum, staffing and professional development, and installation of air conditioners in schools without such. Policymakers would also need to be convinced that the public favors departing from a longstanding tradition of school-free summers for most students. Constituents might value use of summer months for family vacations rather than for year-round schooling. Summer-oriented business owners might object on economic grounds arguing that they would suffer from a loss of teen labor and decline in summer business.

The power of ideas and policy learning contributes to education policy design. Policy ideas float across borders. Policy specialists in different jurisdictions and levels of government communicate via professional networks. The Internet and other technology advances have led to more rapid collection, analysis, and dissemination of education data and research findings that shape policy discourse and design.

Common problems and pressures in education lead different jurisdictions to design common policy responses. Developers of the Common Core State Standards Initiative in the United States examined the academic standards of countries with high-ranking performance on international student assessments such as PISA. They aimed to align the Common Core standards with the standards of such countries.

Policy Types and Instruments

Education policies can be classified according to whether they are regulatory, redistributive, or distributive (Lowi, 1964). Distributive policies are attractive to policymakers who want to claim credit for broadly distributed benefits (e.g., grants for school building improvements). Regulatory and redistributive policies are more controversial. Regulatory policies require or prohibit certain actions (e.g., teacher licensing processes, secondary school graduation requirements, bans on smoking on school premises). Redistributive policies shift resources or power among groups (e.g., contracting with private providers for school services).

There are five types of education policy instruments or tools (McDonnell and Elmore, 1987; Schneider and Ingram, 1990). First, a mandate is a requirement akin to Lowi's regulatory policy. The success of mandates depends on the will and capacity of the target population to comply and on government will and capacity to enforce compliance. For example, a mandate might require schools to include character education in the curriculum. Policy outcomes are shaped by whether schools embrace or resist the mandate and whether and how government chooses to enforce the mandate.

Second, an inducement is the provision of money or other benefit in return for the production of a good or service. Education grants with policy conditions attached are inducements. Third, capacity building policies are similar to inducements but focus on long-term investment.

Fourth, system change policies are similar to redistributive policies because they transfer authority and power from one group to another. Mayoral control of school districts in some

United States cities is an example of a system change policy. Privatization advocates favor system change policies that shift power over education delivery away from the public sector and toward private providers. Finally, hortatory or persuasive tools distribute information, communicate intended norms, and attempt to convince people that a policy is congruent with their values. Signs posted in a school encouraging students and staff to recycle or be kind to one another are examples of hortatory policy.

Policy Adoption

Education policy is adopted by legislative, executive, and judicial institutions at national and subnational levels. Education policy is also adopted in schools and classrooms. Education interests may engage in venue shopping in a strategic effort to find the optimal government setting for pursuit of their goals (Baumgartner and Jones, 1993). While this article does not focus on courts, it is important to note that the judiciary is an important arena for education policy development and enforcement. For example, advocates of school finance reform and civil rights often pursue their agendas in judicial venues. Judicial education policy is shaped by the constitutional and legal context of a jurisdiction.

Actors with authority to adopt policy assess both the logical merit of a given policy proposal and the strength of interest group support or opposition. Policy change is more likely when there is not strong, organized opposition to a proposed policy. However, the power of an idea can trump interest group power. In the United States, policymakers in a majority of the states demonstrated receptivity to the charter school idea and adopted laws permitting charter schools despite strong opposition from traditionally powerful teacher interests.

Policy change is generally more likely to occur during times of robust budgets. However, the economic context may be of little importance when there is policymaker consensus that a policy addresses a strongly held value or right (e.g., ensuring student safety). An intangible yet significant factor that influences policy adoption is policymaker perception of a general climate or 'mood' in a jurisdiction (Kingdon, 2011). For example, policymakers may perceive consensus in favor of increased accountability or competition in the public sector.

Policy Implementation

Policy development does not end with policy adoption. Adoption of an education policy does not ensure robust implementation of the policy as designed. Opponents can alter the policy during the implementation process. Policy implementation outcomes depend partly on the will and capacity of implementers to act in accordance with the original policy design. In federal systems, subnational actors enjoy expertise and implementation advantages that enable them to resist and reshape federal education policies that threaten their perceived interests (Nugent, 2009; Vergari, 2012).

Implementers opposed to a policy may do the minimum necessary to avoid penalties for noncompliance, and they may not want the policy to gain long-term legitimacy. These factors make it important for policy advocates to secure stakeholder input and 'buy-in' during policy design and adoption. Implementation outcomes are also determined by the will and capacity of policy adopters and administrators to enforce the original policy. Effective policy implementation requires a strategic balance of pressure and support. Pressure focuses implementer attention and support provides resources necessary for robust implementation (McLaughlin, 1987).

When policy implementation proves technically or politically difficult, policymakers and administrators may be tempted to dilute the policy or revise timelines for implementation. For example, if a new policy on secondary school graduation requirements results in large numbers of students unable to graduate on time, policymakers may revise elements of the policy or extend implementation time frames.

Research and Policy Development

Despite frequent rhetoric touting data-drive decision-making, the power of values, beliefs, and preferences can rival the impact of research evidence in the education policy process. Stakeholders and policymakers may neglect high-quality studies that yield mixed or cautionary findings in favor of less rigorous research that supports their policy agendas (Goldhaber and Brewer, 2008). Philanthropic foundations that fund research are often less interested in careful, peer-reviewed research than in shaping research findings that support foundation agendas (Henig, 2008). The Internet and other technology advances have led to rapid collection, analysis, and dissemination of education data and research findings that shape policy discussions. Some researchers rush to share their findings with the mass media and policymakers before the studies have undergone scrutiny by experts in a peer review process (Hess, 2008).

The Drug Abuse Resistance Education (DARE) program was created in 1983 in Los Angeles, California. According to DARE, the program has been implemented in a majority of the United States school districts and in more than 40 countries. The program uses trained, uniformed police officers in schools to deliver a 10-week series of structured lessons aimed at developing student skills to resist drugs, alcohol, gangs, and violence. Two decades after DARE was founded, a series of studies and government reports indicated that there were not significant differences in drug use between students who had completed DARE and students who had not.

Despite the volume of research suggesting that DARE was not producing intended policy results, DARE has remained popular. Based on personal experiences and perceptions, many people simply believe that DARE works. They also like the idea that schools are doing something to prevent youth drug abuse and violence, in accordance with the value preference that schools should fulfill such a role. Supporters suggest that DARE has benefits other than reducing drug use, such as promoting good relationships between police officers and students and enabling educators to focus their time and energy on other parts of the curriculum. While some districts discontinued use of DARE, stakeholders defended the program from threats. In

response to criticism, the DARE curriculum has been revised and evaluations of the new program may inform future policy debates (Birkland, 2011).

Class size reduction is another popular policy despite research indicating significant costs and unintended consequences. It requires that resources be allocated to hiring more teachers and providing adequate classroom space. The costs and benefits of these measures may not compare well to other potential uses for the funds such as teacher professional development and curriculum improvements. Interests such as teachers and parents favor class size reduction as a policy reflecting the value of excellence in education. However, other policies aimed at excellence may be more efficient in terms of yielding better returns on the public funds invested.

Multilayered governance and multiple education reform policies implemented simultaneously make it difficult to isolate the effects of a given education policy and assign accountability for outcomes. When a policy does not yield intended results, there may be several reasons for this outcome. There may be flaws in the policy as designed; the causal theory linking policy design and the implementation process may be faulty; implementers may lack will and capacity to implement the policy in a robust manner; actors overseeing implementation may not provide sufficient monitoring, support, and pressure to ensure successful implementation; and, the policy may have been watered down in response to challenges encountered during implementation.

Future of Education Policy Development

Several education policy trends are likely to continue for the foreseeable future. First, education policy development will continue to be influenced by global economic competition and concerns about workforce preparation. Political portrayals of education policies as straightforward solutions to economic problems tend to disregard additional policy areas that contribute to economic conditions (e.g., monetary, trade, tax, wage, and health care policies).

Second, international and transnational organizations will continue to influence national and subnational education policy discussions. Some analysts are concerned that the global education policy discourse is being guided by narrow conceptions of learning. They contend that easily measured traditional school knowledge and basic skills are emphasized to the neglect of a broader range of learning areas such as ethics, aesthetic appreciation, and civic and environmental responsibility (UNESCO International Bureau of Education, 2013). Global movement toward similar education practices could jeopardize the benefits of policy diversity and innovation (Meyer and Benavot, 2013). While economic goals will remain prominent in education debates, advocates of additional education purposes will continue to influence policy agendas.

Finally, developments in computer and mobile technologies will influence policy agendas pertaining to curriculum and education delivery. Technology advances will also facilitate timely collection and analysis of education data and dissemination of information and ideas.

Educational Productivity

Susan J Paik, School of Educational Studies, Claremont Graduate University, Claremont, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Educational productivity is a chief concern for all nations as it impacts human capital and economic growth. Referred to as human productivity, every nation also has a keen interest in developing exceptional talent. An interdisciplinary lens can provide insights as to how homes, schools, time, and other factors affect learning. A 10-factor productivity model provides a new mastery approach in understanding how multiple factors influence productive outcomes. The alterable factors in the model show how constructive changes can help optimize achievement, excellence, and productive giftedness. Helping students to be productive in school and life early on can increase individual and national productivity.

Introduction and Significance of the Topic

Researchers, practitioners, and policymakers have long been interested in promoting educational productivity and striving for national excellence. Educational productivity is an international concern for all nations as it relates to the importance of developing human capital – an essential goal to maintain economic growth. Sometimes referred to as human productivity, every nation also has a keen interest in developing exceptional talent at every level. While colleges and universities need to help train and provide the necessary skills for the labor market, targeting students early on is the key to keeping talent in the academic and career pipeline. Children's success in school and life are the two most important goals for educators and parents, and their overall productivity will undoubtedly affect national excellence (Paik, 2004).

For these reasons, educational productivity continues to be at the forefront of almost every political debate. Educational productivity has been typically measured by achievement tests generally in math, reading, and science. Although standardized achievement tests have been a source of contention in themselves, achievement test scores in light of economics and politics are undeniably pressing issues. Learning, however, may come in many forms, such as academic, creative, behavioral, cognitive, social, emotional, adult success, and other outcomes. All nations are interested in maximizing learning while minimizing costs, time, and other resources. Costs and benefits are important considerations to any endeavor, especially in education. While costs are typically measured by dollars, time and other resources should also be considered in the productivity equation. For example, developing new educational programs, creating an infrastructure to carry out a new program, and training staff can be costly and time-consuming. While these ideas may be innovative, are they worth the costs, time, and resources? Or are there other ways to achieve productivity? Trillions of dollars are spent everywhere across the world on the latest educational fads, new curriculum and instruction, professional development workshops, and teacher-training programs, but the relationship to achievement is not always clear.

For-profit as well as nonprofit organizations try to produce the best results with little resources. While there are some ways to increase educational productivity, many solutions simply require a lot of time and money. Cutting-edge programs may be helpful, but we often overlook the factors that have the most direct impact – the immediate home and school environments of children, especially in the first 18 years of life (Walberg and Paik, 1997). Investing in the home and school in these years may be an economic strategy with a high rate of returns. With little monetary expenses, learning outcomes can be directly impacted by constructive habits, practices, and attitudes. For example, homework time, supportive home environments, good teaching, direct mentoring, self-regulation skills, productive behavior, etc. are simple suggestions, but powerfully generalizable across all students. Moreover, they add value over time. The home environment is considered more powerful than socioeconomic status, especially in the first 6 years of life. The next 12 years in school can also have a tremendous impact in their schooling years from good teaching, curriculum, and other school factors (Walberg and Paik, 1997). Eighteen years of attentive support and skill-building for every child before they go to college could dramatically influence the overall labor market. Supportive learning environments, practices, and conditions in these critical years should not be underestimated. Research has shown that early investments in children can make for large differences over time and can increase educational and human productivity.

The purpose of this article is to (1) discuss educational productivity and the importance of achieving excellence at the individual and national level, (2) provide an interdisciplinary lens (i.e., economic, educational, psychological, etc.) in understanding how home and school environments can impact productivity, (3) present an international perspective in terms of time investments, (4) describe a new mastery model of educational and human productivity, and to (5) conclude with research, practice, and policy on alterable factors that encourage students to be productive in school and life.

Home and School Environments: Economic Investments

Interdisciplinary perspectives provide a wide lens in assessing problems and finding strategies. This article presents primarily

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92076-2

educational and psychological research, as well as other disciplines including economics. Educational productivity viewed through an economic lens can provide great insights in understanding and explaining human behavior (Becker, 1976). Economic perspectives can help illuminate what is required for excellence for individual and national productivity. More specifically, economists provide a practical understanding of time, money, energy, and other resources. From the early teachings of Adam Smith's *Wealth of Nations* in 1776, economic principles can help explain how human, social, and cultural capital contribute to economic growth and educational productivity.

Common sense tells us if we spend more, we get more … So, does more spending mean higher educational productivity? Many researchers would disagree, including James Coleman, Eric Hanushek, and James Heckman. James Coleman, a famous sociologist, is known for the 'Coleman Report' in 1966. Based on one of the largest studies with more than 650 000 students, he found that learning does not depend on the amount of money spent on schools, but what students bring to school that makes the difference. Referred to as social capital, he found that student background and socioeconomic status were more contributing factors. The study also found that good teachers and schools also impacted learning. Decades later, Eric Hanushek (1994), a leading economist and scholar in the field of educational productivity, found that school learning should not be underestimated. While home environments are indeed essential, quality schools and better use of resources can make a large difference in educational productivity. Hanushek studied the effects of educational spending on schools (i.e., teachers, class sizes, and other school resources) and found little to no influence on student outcomes.

More recently, Nobel Prize recipient James Heckman and Dimitry Masterov (2007) analyzed data from several preschools including the well-known Perry Preschool Project, a 40-year longitudinal study. The experimental study randomly assigned 123 at-risk African-American 3- and 4-year olds into a treatment and control group from Ypsilanti, Michigan. The treatment group received early childhood care and education, while the control group was not exposed to any treatment. The study found positive long-term effects for those in the treatment group. The results showed more individuals were employed, more individuals graduated from high school (particularly females), and crime was lower, resulting in fewer arrests. Moreover, the study found that schooling and workforce outcomes had higher economic returns. Some additional findings for education included reduced tuition subsidies and pupil–teacher ratios, and less demand for adult literacy programs, public job training, convict rehabilitation programs, and police expenditures. Heckman's productivity argument is that investing in young children even before kindergarten is an economic growth strategy.

Since the family unit has deteriorated in the US and other countries in the past few decades, early childcare support is one way to supplement the role of the family, especially for disadvantaged communities. Based on the cost–benefit analysis of their findings, early investments not only provide benefits to society, but can also enhance economic vitality and international competitiveness.

Educational Productivity in International Context: Time Investments

Given the interest in educational productivity, much research on this topic comes from the US perhaps because of the efforts in trying to improve achievement and costs over the years. International and national trends tell us that American productivity continues to remain stagnant though per-student schooling costs are higher in the US than in most other industrialized countries. Elementary and secondary schooling in the US might be one explanation for the achievement differences among industrialized countries. By the end of secondary school, the US generally falls behind many of their Asian and European counterparts. The achievement gap widens from elementary to secondary school. Researchers have examined school expenditures, class sizes, teachers, teaching, curriculum, and other indicators in understanding elementary, middle, and secondary schools with differing results.

Based on international comparisons, East Asian countries appear to fare well. Japan, Korea, Hong Kong, Singapore, and Taiwan have all been top performers in past international achievement tests. The latest 2009 Program of International Student Achievement (PISA) results reported that China was the top performer out of 65 countries though it was their first time to compete internationally. Researchers have sought to explain the achievement differences in the learning environments and practices of East Asian and U.S. students. One striking difference is the use of time in and out of school. U.S. President Obama stated, "Our children spend over a month less in school than children in South Korea. That is no way to prepare them for a 21st century economy" (Edu in Review, 2009). U.S. policymakers have since considered extending instructional time per school day and year.

Time usage can indeed impact individual and school productivity. In the first 18 years, home environments play a strong role as parents nominally control roughly 92% of the student's waking time, and schools strongly influence the remaining 8% of time spent in school (Walberg and Paik, 1997). However, East Asian students spend more time in their school year. In the case of South Korea, Korean students are in school for about 222 school days compared to 180 U.S. days. For U.S. school years, 12 years of schooling (180 6-h days) is equivalent to 12%. In comparison, 12 years of Korean schooling (222 8-h days including Saturdays) is equivalent to 19%. The estimated time in school is about 50% more for Korean students (Paik, 2001).

After-school hours also amount to different learning experiences for East Asian and U.S. students. Homework time, private tutoring, and television viewing appear to influence learning outcomes. While the focus of many after-school programs is on remediation in the US, after-school programs or private tutoring have a different meaning in East Asia. Considered the norm for most East Asian students, Korean 'hagwuan,' Japanese 'juku,' and Chinese 'buxiban' focus on academic enrichment or getting ahead. This additional study time with extra classes or homework time is estimated to be 4 h/day for East Asian students, while U.S. students average one extra hour per day. With minus 40 school days and 3 h less study time, U.S. students watch television on average of 3 h/day (Walberg and Paik, 1997). In calculating total time in and

out of school, many East Asian students, in particular Korean students averaged 100% more learning time from ages 6 to 18 (Paik, 2001). Developing skills in the first 18 years is bound to have some impact on educational productivity nationwide. Time is another precious resource and how it is spent can make for large differences in individuals, schools, and nations.

Human Productivity: Developing Exceptional Talent

In order to be globally competitive with the growing demands of technology, specialized talent is more important than ever to all nations. Nobel prize winning Gary Becker's (1976) work informs us that not only education, but specialized training enhances human capital. Although Adam Smith's economic principles in 1776 on specialization and division of labor referred to a different context of efficient production, the general notion of developing expertise as critical to productivity can be broadly applied here. There is an economic need for specialization in all disciplines. Human productivity (i.e., achievement, accomplishment, eminence) can provide a national platform for excellence. Given the rapid modernization in industrialized countries, a highly skilled workforce is in demand. Encouraging students to enter technical careers, such as sciences, technology, engineering, mathematics, etc., and other specialized fields are important to today's economy. Moreover, despite the discipline, exceptional talent development must be developed strategically.

When and how do we encourage a steady pipeline of talent to enter specialized fields? Generally, for most students, the pipeline ends at college. Therefore, students entering pipelines before or during elementary school provide the most promising outcomes. Research has found that many students start thinking about careers and professions as early as elementary and middle school. By now it is no secret that investing in our students early on will undoubtedly impact individual and national productivity. Referred to as 'Matthew Effects' or accumulative learning by Robert Merton in 1968, early investments will yield greater dividends and higher productivity. In Heckman and Masterov's (2007) study, they describe preschools as "the best job training program" where they learn 'soft skills' such as paying attention, learning social skills and new experiences. Since skills and abilities are linked to economic and social problems, the study showed that early job training did have high benefit–cost ratios and rates of return. Early investment is a strategy of efficiency as talent specialization can later achieve even greater productivity.

Children spend the most time at home and school before they go off to college. How we encourage students during these years can make a tremendous impact. A comprehensive model to understand the factors that influence achievement is needed for some additional strategies. Are student success and talent development scalable? Though not a simple answer, any scalable success can only happen when parents, teachers, and key stakeholders play a supportive role in children's education. There are many strategies, but a comprehensive model that includes individual, home, school, time, and other factors might provide an initial start in understanding productivity.

Productive Giftedness: An Early Investment Mastery Model

The productive giftedness model (a 10-factor productivity model) is a comprehensive and systematic model to understand educational and human productivity (see **Figure 1**) (Paik, 2013). In borrowing economic language, how can we make learning more 'productive?' or make giftedness, talent, or excellence more productive? While the model is largely psychological, it provides an interdisciplinary lens as illustrated earlier through economic, educational, and other perspectives. From an economic standpoint, research studies show that early investments of learning and skill-building can produce positive outcomes over time. In the same vein, the model advocates that accumulative learning can be more advantageous as it can impact productive outcomes. However, it is important to note that learning and talent development are not static, but an ongoing process for all individuals. While developing skills early on is ideal, learning can happen at any time and still be made productive. In cases where students may not have optimal conditions or environments, other factors in the model can be distinctively applied to supplement learning at different stages. Learning must also be considered in the context of the area of specialization.

The productive giftedness model is a mastery model where individual skills and expertise can be nurtured (Paik, 2013). The 'nature versus nurture' debate continues and more recently has been referred to as 'mystery versus mastery' (Matthews and Foster, 2006). The mystery model uses a traditional lens to explain innate abilities, but the mastery model focuses on nurturing and developing ongoing skills. Mastery learning has traditionally been derived from the classroom experience or school learning. For example, mastering each step or concept in the curriculum is required before moving to the next level. With allocated time on task, students can pace their own learning. In the current model, the definition of mastery learning or skill-building extends beyond the walls of the classroom. Time in school and out of school can also affect development, learning, and expertise. Although teachers play an important role,

Figure 1 Productive giftedness model.

parents, mentors, experts, and peers also affect skills, habits, and attitudes.

Given its practical approach and accessibility, the model suggests that achievement and accomplishment are possible for all students, even those from disadvantaged communities. The nature argument suggests that individuals are born with talent, while others argue that one must find and develop their own talent. In both cases, nurturance is necessary for fruition. The factors in the model can still be applied distinctively across individual students since learning and development are an ongoing process. Based on the author's previous work and other studies including Walberg's earlier work, the model is generalizable across demographic variables, such as socioeconomic status, age, gender, race, and diverse cultures (i.e., the US, East Asia, Europe, and African-American, Latino, white, other groups in the US) (Paik, 2001; Walberg, 1984; Walberg and Paik, 2005). In general, the model provides a comprehensive and practical approach in assessing individual differences. Mentoring or support programs were also added in the new model as extra measures of support as they can be helpful especially for students coming from less than optimal conditions (Paik, 2013). The model calls for different stakeholders in different disciplines to work together and encourage productive giftedness among students.

Defining Productive Giftedness

Productivity is important in every field, especially in advancing education and developing talent in specialized fields. There are many students with potential, but too few individuals successfully stay in the academic and career pipeline. Giftedness is defined broadly in this context, and such terms as talent, expertise, success, or excellence have been used interchangeably. Despite the use of terminology, 'giftedness' is best understood when made productive (Walberg and Paik, 2005). Productive giftedness is not just potential; it is defined as achievement, accomplishment, and can lead to adult eminence (Paik, 2013). As defined by the author, productive giftedness is inclusive of both high achievement (intelligence or IQ) and high ability (creativity or other domains). Leadership, another form of productive giftedness, is also a productive outcome where researchers have now begun linking early experiences to leadership development (Reichard and Paik, 2011). For the purposes of this article, while creative accomplishment and leadership are important areas of research, the focus of this article will be on academic achievement and high-achieving individuals.

Given the mystery versus mastery debate, the term, 'productive giftedness' is representative of both effort and ability respectively (Paik, 2013). The two terms represent somewhat contradictory ideas, and in fact, some cultures value these concepts differently (i.e., Eastern vs Western ways of learning – effort vs ability). Despite the differing terms, together they represent an important concept that ability can be nurtured. Consider, 'unproductive giftedness' for a moment. One might understand these terms as talent without any direction or efforts. Since learning and development are an ongoing process, all forms of giftedness and talent need to be nurtured. Productive giftedness can be developed and sustained by hard work, perseverance, focused motivation, and other traits (Paik, 2013). Educators and other stakeholders need to take the perspective that all students can achieve when provided with opportunity, support, and resources (Paik and Walberg, 2007). A commitment of their own time and efforts are also keys to their own growth. Teaching children the value of productive giftedness or sense of accomplishment early on can indeed impact educational and human productivity.

Walberg's Productivity Model: School Learning in Context

Although influenced by Carroll, Bloom, and Glaser's school-learning models, Walberg's nine-factor productivity model is inclusive of more environmental factors. The nine factors include the following: (1) development, (2) ability, (3) motivation, (4) quality of instruction, (5) quantity of instruction, (6) home curriculum, (7) social climate of the classroom, (8) peers, and (9) television viewing. The productivity factors have been found to be consistent and generalizable in a number of studies. Specific definitions and concepts of the model can be found in Walberg (1984).

The productive giftedness model builds upon Walberg's earlier work, as well as other seminal research in this field. Walberg's model was selected as the basis of the current model for several reasons. First, compared to other models, the productivity model is one of the most comprehensive models. A multiple-factor approach can help explain individual differences. Second, the model was empirically developed based on a meta-analysis of roughly 3000 studies. Few models and theories have been empirically developed. Third, research studies including the author's own work have found the model to be generalizable with regard to aptitude, instruction, and learning environments (Paik, 2001; Walberg, 1984; other studies). Fourth, the multiple-factor model consists of alterable factors that can impact learning outcomes. Walberg's model provides an empirical basis in understanding educational productivity. While there is no perfect model and none are without limitations, a ten-factor model provides a new mastery approach to understand productivity.

Productive Giftedness Model: 10 Productivity Factors

Along with other theories and models, Walberg's model was intended as a school-learning model. The productive giftedness model has been revised to be inclusive of learning and talent development for early and later success. Several factors share similar terms with Walberg's model, but the underlying concepts have been broadened and adapted to the new model. New terms, concepts, and definitions have also been included in the model. To provide an overview of the model, the factors are briefly described in this section. While all factors of the model are important and interrelated, given the centrality of family and schooling in this article, the following section will conclude with the importance of alterable practices in the home and school.

The multiple-factor model is considered largely alterable, which refers to practices that can be constructively changed, especially in home or school environments. To some degree, adults and students themselves can alter some of the factors. When optimized or altered, they can influence productive outcomes. Alterable practices, attitudes, and habits can include

such examples as homework, study time, curriculum, goal-setting, productive behavior, reading more, self-regulation skills, attitudes, etc. Parents, teachers, and other adults can provide supportive and conducive learning environments for all students.

The model shows that a comprehensive approach is likely to be the best approach, but it is important to note that all factors need not be present to influence productive outcomes. Learning is dependent on all factors, but factors can compensate for one another. For example, use of time (quantity of instruction or extracurricular time) will be different for students given the range of motivation or ability across students. Development or age is also an important factor in terms of the type of instruction they may receive in the classroom. All factors are interrelated and work together, but may be present with differing rates or processes depending on students' interests, abilities, developmental stages of growth, and environmental factors. Environmental factors may also directly and indirectly supplement some of the factors. Homes, schools, peers, and the presence of other adults differ for all students.

Productive Outcomes

Student success is described in the model as *productive outcomes*, and it is further operationalized as *achievement* (generally IQ/intelligence) and *accomplishment* (creativity, other domains). Productive giftedness can be further defined as distinction among peers; they can be broadly operationalized as test scores, awards, honors, competitions, occupation, affiliation, status, etc. Other productive outcomes can include *eminence* or *leadership* (relevant to all domains). Though rare, achievement and accomplishment in the school years can lead to eminence in adulthood. Adult success and other outcomes can also be characterized as productive outcomes. Although *leadership* is not included in **Figure 1**, leadership is another productive outcome for many high-achieving and high-ability individuals. Since the focus of this article is on achievement, the remaining sections will discuss how the model can increase learning and achievement.

Individual Aptitude

There are three factors under individual aptitude: *development, ability, and motivation*. From a lifespan perspective, *development* and learning are continuous. Defined as age or stage of maturation, this factor can be helpful in studying early and later success at different stages. The model can support prospective or retrospective studies for childhood, adolescent, or adult outcomes (Pre-K to post-college) depending on the population and research inquiry. *Ability* has been expanded to incorporate achievement and *other* ability tests (if applicable) depending on the domain-specific area. For academic achievement, standardized test scores have been typically used to measure learning outcomes. Grades and other measurable productive outcomes as noted earlier can also be considered when assessing ability. *Motivation* or *focused motivation* can impact productive outcomes. Specifically, *focused motivation* is defined as "undeterred, intentional perseverance with an end goal or product in mind" (Paik, 2013). Focused motivation is described as intrinsic and/or extrinsic depending on the goals or product. Perseverance, mind-sets, resilience, self-regulation, personality traits, and attitudes are important factors that should be examined. The psychological model naturally lends itself toward a positive psychology lens in studying the strengths of successful individuals, such as perseverance, determination, hard work, and other positive traits.

School Factors

There are three factors in this category: *quality of instruction, quantity of instruction, and school–classroom climate*. The *quality of instruction* refers to excellent teaching, curriculum, content matter, assessment, evaluation, cooperative learning, and any other relevant information that adds to the quality of the school and classroom experience. Much research shows that teachers and what they do in the classroom can directly make a difference. The *quantity of instruction* is defined by the amount of time spent on learning or years in schooling. School hours per day and year, as well as instruction time can make a difference in learning. Schooling years and degrees can also impact learning outcomes. The *school climate* is defined as any school or classroom experiences or characteristics that affect the overall morale of the school or classroom environment. Sociocultural factors, such as type of school, neighborhood, or community, can also provide helpful information.

Environmental Factors

There are four environmental factors: *home, mentoring, peers, and extracurricular time*. The *home environment or* 'curriculum of the home' is a central factor to learning. Parental involvement, practices, and any other home-related information are central to productive outcomes. Demographic information should also be considered, such as culture, race, language, socioeconomic status, parents' education, gender, and any other relevant information. These characteristics are important as they inform us about the role of opportunity for many students, especially those coming from disadvantaged communities. *Mentoring* can involve formal or informal coaching, expertise, programs, or other supportive opportunities (Paik, 2013). Guidance, knowledge, or skill-building in any domain-specific area can be helpful. Mentoring is more common among older students or adults, but there are exceptions and can occur at any age. In the case of disadvantaged or marginalized students, mentoring provides extra support for individuals to stay on track and receive additional guidance. *Peers* can influence attitudes, beliefs, and experiences, especially during adolescence. Peer relationships can provide valuable information at different stages of learning and talent development. *Extracurricular time* is broadly defined as time spent on activities mainly outside of school learning. These activities can be academic, recreational, domain-specific activities, hobbies, sports, participation in places of worship, supportive programs, clubs, etc. Television viewing, gaming, and other forms of technology (i.e., Internet, electronic communication, blogging, etc.) can be time-consuming activities. How students spend their time after school can be informative in understanding individual productivity.

Nurturing Productive Giftedness: Alterable Home and School Practices

Research has found that stimulating home and school conditions and experiences during childhood were strong indicators of later success (Bloom, 1985). Excellence and expertise cannot be fully developed without practice, parental support, dedicated teachers, and good mentoring. Bloom (1985) studied the talent development of world-class neurologists, mathematicians, pianists, sculptors, swimmers, and tennis champions. From the early years, he studied the involvement of parents, teachers, and expert instruction. Bloom later reported, "What we found were exceptional conditions, not exceptional kids." Learning environments vary from home to home and from school to school, but parents, teachers, and other adults should recognize that these environments are alterable and significant on early development and learning.

Altering the Home Curriculum: The Role of Parents

Research has consistently found parental involvement as a significant factor regarding learning, well-being, and other productive outcomes. International studies, such as the Trends in International Math and Science Study and PISA, have confirmed the home environment as strongly related to student success across all countries. Given the concerns of educational productivity, family environments continue to be an important factor in the productivity equation. In the US, national reforms have emphasized the importance of parental involvement, family–school partnerships, and healthy families. Parents are the first and most influential teachers where the curriculum of the home matters more than socioeconomic status. Motivation and learning are also significantly correlated to families and home environments (Walberg, 1984).

National reforms in the US have emphasized not only the importance of parents, but also the value of time for students. In the home, parents can engage students constructively, provide the necessary guidance and feedback, and create a learning environment conducive to learning. Alterable factors include providing stability and routine of family life and healthy parent–child relationships to help support and guide their children, clear expectations and supervision, discipline and affection, extra lessons and monitored time, family field trips, parent–child conversations about school or peer activities, encouragement of leisure reading, engaging them in interactive projects, family time, and discussion of books and television, self-regulation skills and goal-setting. The constructive habits, practices, and conditions optimize learning and long-term goals (Redding, 2003; Walberg, 1984).

Altering the School and Out-of-School Curriculum: The Role of Teachers and Mentors

Given the importance of teachers, billions of dollars have been given to teacher reform initiatives across the world. Similar to home environments, children need conducive classroom environments. Good teachers matter. Teachers have great influence on their students, especially for students who may be coming from homes with less than optimal conditions. Research studies consistently show that teachers have a significant impact on achievement. While educational expenditures or other school policy-related matters are less direct, teachers can indeed directly impact student outcomes.

Teachers can use curriculum and any other classroom experiences to engage and expose students to various topics. Engaging students in projects with real-life problems can also enhance their problem-solving skills. Alterable factors include teaching methods and curriculum, book selection, constructive homework, projects, or programs that enhance learning and other skills, career day for early exposure to different disciplines or occupations, interactive group work or projects, high expectations for each child, and communicating and developing relationships with parents for extra support. What teachers do in the classroom can motivate and encourage students to be engaged in their own learning.

Parents and teachers obviously play an important role, but high-achieving students may need differentiated or expert instruction to provide the appropriate knowledge and skills that parents or teachers may not be able to provide. Research shows that mentors and other supportive programs are extremely helpful for all students, especially disadvantaged students. Mentorships can provide the extra support in a domain-specific area and life in general. Mentorships can take on a formal or informal role providing expert knowledge, skills, and advice at different stages (Clasen and Clasen, 2003; Jacobi, 1991). Mentoring practices may vary in different fields, but encouragement and guidance are helpful to all students. Bloom's (1985) study found that every student worked closely with parents, teachers, and mentors. These supportive communities were critical at every stage during the early, middle, and later years. Clear expectations and encouragement by at least one caring adult can make a tremendous impact on student success.

Conclusion and Implications

Educational productivity requires achieving excellence at the individual and national level. An interdisciplinary and international perspective can provide new insights into how homes, schools, and time factors impact productivity. The productive giftedness model provides a new mastery approach in understanding how multiple factors influence productive outcomes. The alterable factors in the model show how constructive changes can help optimize excellence, expertise, and productive giftedness. Helping students to be productive in school and life early on can increase individual and national productivity.

Children spend the most time with their families (0–6 years) and in schools (6–18 years) in their first 18 years. The accumulative advantage of Matthew Effects shows that early investments of time can optimize long-term productivity in life. Parents, teachers, and other adults need to foster learning in the home and school learning environments. Mentors, experts, and other supportive programs can provide extra support and accountability for student success. While this article did not focus on peers, their role can also be critical in the learning and development process. Supportive communities require all stakeholders to work together where resources, support, and opportunities can impact not just one, but larger numbers of children and youth. The productive giftedness

model suggests that achievement and excellence are possible on an even larger scale.

Abstract

This article focuses on the social organization of education research as a social science field in the United States and considers its development and scope worldwide. It examines the emergence of education research, the structure and context of training in the field, doctoral degree production, characteristics of education researchers and their location in the labor force, the formal organizations of professionals in the field, and patterns of knowledge dissemination. The article also includes salient comparisons to other social science fields.

Introduction to the Field of Education Research

This article focuses on the social organization of education research as a field of study in the social sciences. The emphasis is on education research in the United States, although attention is paid to the development and scope of this field worldwide. The distinctive identity of education research is reflected in its history, presence in higher education institutions, the theoretical perspectives and modes of inquiry that inform knowledge production, characteristics of advanced degree training, the formal organization of professionals in the field and their locations in the labor force, and patterns of knowledge dissemination.

Education Research as a Social Science

Education research[1] is the social science field that studies education and learning processes and the human attributes, interactions, organizations, and institutions that shape educational outcomes. The field embraces the full spectrum of social scientific methods used in other fields and also has driven the development of social science tools and methods.[2] Scholarship in this arena seeks to describe, understand, and explain how learning takes place throughout the life cycle and how formal and informal processes of education affect students' learning and attainment. While considerable attention is paid in education research to the processes of developing critical reasoning skills and knowledge, the field also addresses how educational contexts affect social skills, beliefs, and behaviors.

Like other social science fields, education research is directed to building fundamental knowledge through rigorous methods and the sound application of that knowledge. Its focus is on a major social institution of society – education – in its various organizational forms and structures. It also, however, emphasizes education and learning at all levels of analysis and contexts from early childhood through adult and workforce education. In that sense, education research is analogous to some other fields in the social sciences such as economics or political science that similarly focus on major social institutions and processes; that is, the economy and polity (Levine, 2003).[3]

Emergence of Education Research

Education research as an arena of social scientific inquiry can be traced back to the last decade of the nineteenth century and the first decade of the twentieth century. Historians have observed that the development of the social sciences was influenced by the social reform and social service impulses of the post-Civil War era (Furner, 1975; Haskell, 1977; Ross, 1991). Education research, along with other evolving social science fields and disciplines at the time, emphasized producing useful information to address the challenges of industrialization and a society coping with issues of poverty, race relations, and new immigrant communities. Sociology, for example, emerged during this period to "put 'social science' to work" on social problems (Calhoun, 2007), just as there was a call for a 'science of education' and a 'new profession' to produce facts essential to helping public schools deal with their new roles and responsibilities (Mershon and Schlossman, 2008).

The professionalization of the social sciences essentially occurred within the academy at a time of growth in higher education. As Brint (1994) pointed out, the period of urban industrialization during the late 1800s was ripe for all types of professionalization activity, including the development of modern social science. At that time, departments of education were established in universities (e.g., New York University, 1890; Stanford University, 1891; University of California, Berkeley, 1892), with University of California, Berkeley conferring its first PhD degree in 1898. Education research began to flourish in universities during this period, but it did not develop as distinctive an identity as did other social science professions.[4]

In these early years, the location of influence and leadership for education research was not as exclusively situated within universities as it was for other social science fields. For example, social science associations like the American Political Science Association and the American Sociological Association (ASA) were founded in 1903 and 1905, respectively, largely by academics. In contrast, the establishment of an educational research association in 1916, the National Association of Directors of Educational Research (NADER)[5], was largely driven by directors of bureaus of education research primarily located in city public schools. These founders placed strong emphasis on surveys, systematic information, quantification, and measurement as did their counterparts in universities.

While they worked closely with academics, their interest in having public school administrators use scientific research led them to conceive of and press for the establishment of NADER.

Over time, along with the growth of education faculty, university-based research training, and research bureaus located in universities, the role and influence of academics within NADER expanded. NADER was initially founded as an organization within the Department of Superintendence of the National Education Association (NEA). By 1922, it officially changed its name to the Educational Research Association of America and, by 1928, to the American Educational Research Association (AERA). During the next decades, the culture and identity of the organization and the field became much more academic – with AERA officially separating from NEA in 1968.[6]

Disciplinarity and Interdisciplinary Linkages

From both inside and outside of the field, education research is generally depicted as an interdisciplinary social science (see, e.g., Lagemann and Shulman, 1999). In addition to indicators of its freestanding emergence, in its early development, it was both shaped by and embedded in other social science fields, especially psychology. While education research is situated in the social sciences, it also has strong interdisciplinary links to the humanities, in particular history and philosophy, and to mathematics and the physical sciences (in part because of the emphasis that these sciences have placed on unraveling the dynamics of science learning).

Overall, based on its history and functional properties, education research might best be described as both disciplinary and interdisciplinary in its origins and trajectories. Permeable at its boundaries and broad in its networks, education research includes features of traditional disciplines (e.g., dedicated journals, scholarly organizations, graduate training) that help to support and advance building cumulative bodies of knowledge (Levine, 2003). Education research, however, also benefits from its adjacency and synergism with other disciplines and subfields within them. For example, work on expectancy effects in psychology and policy implementation in political science has, respectively, informed studies of student achievement and of the impact of educational reforms.

In the twenty-first century, much attention is anchored on knowledge integration and building knowledge across all fields of science. In general, in social science fields, distinctions between interdisciplinary and disciplinary are neither well understood nor readily resolved. As Calhoun and Rhoten (2010: p. 103) observed, "The distinctions among the social science disciplines are historically forged and largely arbitrary … They may be more matters of style than method – characteristic structures of attentions, values, and ways of solving problems – but they are jealously defended and also maintained simply by habit and social networks."

Structure and Context of Training

Training in education research essentially occurs at the doctoral level. At the undergraduate and master's levels, students primarily pursue education degrees in order to enter the teaching profession in elementary or high school settings. In general, undergraduates in the social sciences are less anchored on scientific careers within their fields than in other fields of science (Levine and Bell, 2015). At the bachelor's level in education, programs are focused on teacher preparation, and thus even a lower proportion of students receive initial exposure to research or to becoming research professionals. Over the last 10 years, some growing interest in undergraduate programs is evident.[7] The University of California, Berkeley and the University of California, Irvine are examples of institutions that offer concentrations in education research, with the former having a minor and the latter introducing a major in education sciences commencing in 2014. Master's degree programs in graduate schools of education are also largely directed to professional preparation for teaching. In some fields of education research, however, master's programs prepare graduates for applied research positions (e.g., MA programs in educational measurement or testing or in educational policy).

Most education research professionals receive their preparation and training in graduate schools of education.[8] Education is also a specialty concentration within other social science (e.g., sociology of education) and humanities (e.g., history of education) disciplines, but the vast proportion of doctoral degree production occurs within schools of education. The number of US universities offering a doctorate in an education research field is not precisely known, but was estimated at 133[9] by Levine and Shepard in undertaking the most comprehensive study of education research doctorate programs to date in the United States (DocStudy).[10]

Education Research Doctoral Preparation

Education research doctorate programs prepare a substantial number of doctorates each year. One important distinction between doctorate education in education research and other social science fields relates to the size of degree production. Disciplines like sociology, political science, or economics have general preparation programs where students specialize in one or another area. In education research, where doctoral production is much more sizable, the structure of training is typically more organizationally complex, with dedicated doctorate programs in identifiable fields.

Levine and Shepard emphasize that the vast majority of graduate schools of education have separate programs in more than one field, although they vary in how they structure their doctorate programs. The analog they use for doctoral training in a field as large as education research is to the life sciences where overall there is also high doctoral production and where dedicated doctorate programs can span fields from genomics to entomology (Levine and Shepard, 2008).

Taxonomy of Education Research Doctorate Programs

An important window on education research comes from a specification of the fields that train doctorates through identifiable programs. Levine and Shepard (2008, 2013) developed an empirical taxonomy as part of their assessment of education research doctorate programs. Based on systematic research of all identifiable education research doctorate programs, they arrived at a taxonomy of 17 fields that produce

almost all of the education research doctorates in the United States.

Levine and Shepard (2013) point out that the number of research doctorate programs in each of the 17 fields varies – from fields like curriculum and instruction with a very large number to those with a smaller number of programs like educational policy.[11] They report that the fields engaged in doctoral preparation range from those closely aligned to teaching and the curriculum components of education (including in reading/literacy, mathematics, and science) to those more anchored on learning and developmental processes and the broader contexts that shape education or in which learning occurs. They also observed dedicated doctorate programs in educational measurement and statistics.

Doctorate Degree Production

Overall Patterns

Dedicated education research doctorate programs support the production of a very large number of doctorates each year. Table 1 shows doctorates awarded in education research and six other social science-related fields from 1987 to 2012. Over this 25-year period, the number of education research doctorates produced remained sizable and steady at approximately 2500 per year across fields.[12] Adjusting for clinical psychology, fields of psychological research were generally comparable to education research in doctorate production at approximately 2000 per year. In comparison, the other social sciences produced 1000 or fewer doctorates per year over the same 25-year period, with only modest growth in certain fields over time.

Diversity and Doctoral Production

Over the 10-year period from 2002 to 2012, women earned approximately 70% of the doctorates in education research (S&ED, 2012: Table 15). This high proportion reflects an overall trend in the expansion of doctorates earned by women since the 1980s. The National Science Foundation (NSF) does not report on historical trends in the gender composition of those earning doctorates in education research. Overall patterns within the social sciences show an increase of women receiving doctorates over time – from slightly more than one-third in 1982 to nearly 60% in 2012 (S&ED, 2012: Table 14). There is also substantial variation across fields. In 2012, women earned 63.4% of doctorates awarded in sociology, and 71% of doctorates in psychology. In 2012, in education research, women earned 70.4% of the education research doctorates (S&ED, 2012: Table 16).

In 2012, approximately 25% of recent doctorate recipients in education research were persons of color (S&ED, 2012: Table 24).[13] African-Americans were the largest racial/ethnic minority group, earning 12.9% of the doctorates, followed by Hispanics earning 6.3% of the doctorates, and Asians earning 4.6%. In comparison, across the social sciences, approximately 22% of the 2012 doctorates were persons of color. As reported by Levine and Bell (2015), there is considerable variation in minorities earning doctorate degrees in the social sciences by discipline. Social science fields ranged from those with overall low numbers of minorities earning doctorates (anthropology and political science with 15.9% and 15.7%, respectively) to those more similar to education research (psychology, economics, and sociology with 21.4%, 23.5%, and 27%, respectively) (S&ED, 2012: Table 24).

Table 1 Doctorate degrees awarded in seven social science-related fields for selected years, 1987–2012

Sources: National Science Foundation, 1999. Doctorate Recipients from United States Universities: Summary Report 1997, Appendix Table B-1; S&ED, 2012. Doctorate Recipients from U.S. Universities, Science and Engineering Doctorates: Detailed Statistical Tables, Table 13.

Characteristics of the Profession

As noted above, the education research profession is sizable. It is composed of social scientists, students, and other scholars engaged in research in arenas reflecting both the scope of the field and the numbers trained to pursue professional research careers. Currently data are limited on the size, scope, and parameters of this research community; preparation for the education research profession, career patterns, and trajectories; and areas of stability and change over time (Levine, 2003; Ranis and Walters, 2004).[14] However, imperfect, the AERA membership database provides the broadest single overview available of the education research profession as currently constituted.[15]

General Overview

Just taking the United States, the total number of active education research professionals is not known but might be estimated at 50 000.[16] The AERA membership is an undercount of active professionals because some proportion of the community does not join professional organizations or joins specialized research organizations. In 2012, AERA reported over 25 000 members, with 63% regular members, 27.4% graduate students, and 4.8% international affiliates, among other categories.[17] The sizable proportion of graduate students (and the stability of these numbers over time) reflects an attraction to the field and to the continuing engagement of successive cohorts in it.

In any field, one indicator of an identifiable research community is a shared professionalization experience within a single field. The AERA membership data suggest that to be the

case. The vast majority – 74.9% – reports their primary discipline as education rather than a separate social science or other discipline.[18] Further, professionals in this field dominantly have a doctorate degree. Within AERA, the 66.9% with doctorate degrees and the 27.8% with master's degrees generally reflect the relative proportion of nonstudent and student members.

Also, the patterns of participation of education researchers within AERA reflect the major areas of research emphases. AERA is structured into 12 divisions. The four largest divisions in terms of membership are teaching and teacher education, learning and instruction, the social context of education, and measurement and research methodology. Each has memberships ranging from approximately 3000 to almost 6000. As would be expected, these generally correspond to some of the major fields within education research where there are also dedicated doctorate programs (Levine and Shepard, 2013).

Demographic Profile

The demographic backgrounds of AERA members also provide a window on the composition of the field. It is consistent with the profile presented above for recent doctorates. Of the AERA membership, approximately 65% are female and 35% male, reflecting general patterns and trends in some (e.g., sociology and psychology), but not all, of the social sciences (Levine and Bell, 2015). In terms of race and ethnicity, 67.4% of the AERA membership is non-Hispanic white, 10.7% is Asian/Pacific Islander, 8.4% is African-American, and approximately 6.1% is Hispanic. As seen in other fields, less than 1% is American Indian or other Native American.

Education Research Professionals and the Workplace

Sectors of Employment

Constructing a clear and complete picture of education researchers in the US labor force remains challenging. An important limiting factor is the way in which education fields are classified in national surveys and statistical profiles of employment in scientific fields. For example, the NSF's Scientists and Engineers Statistical Data System classifies all education fields (except math and science teacher education) as 'nonscience and engineering fields.' Thus, education researchers are not represented in social science occupation statistics.

The NSF data on postgraduation plans of doctorate recipients provide some useful information on employment sectors (S&ED, 2012). Like recent doctorates in other social science fields, a substantial majority of education researchers are employed in academic institutions. An examination of the 2012 data shows that, among those who had secured employment and planned to enter the workforce immediately, 62% planned to work in postsecondary institutions. The employment destination for the second largest segment of this cohort (22%) was primarily elementary or secondary schools. Much smaller sectors of employment are nonprofit organizations (which include research and development institutions), industry/business, and government with 6.4%, 5.6%, and 3.9%, respectively (S&ED, 2012: Table 65). In the same year, 60.8% of new social science doctorates moved into the postsecondary education sector although concentration in this sector is considerably higher for some disciplines than for others.[19]

The AERA membership database helps to complete this picture. These data reflect the entire membership and not just those entering employment after their doctorate. Education research professionals are dominantly in universities (79.2%), with the next categories being considerably lower (school systems at 7.2%, R & D organizations at 3.9%, government at 1.4%, and industry/business at 0.6%). The presence of education research professionals in universities is higher than for professionals overall in science and engineering fields (45%) and more comparable to some (though not all) fields of social science, including political science, sociology, and anthropology (see Levine and Bell, 2015). Indeed, the AERA data are consistent with the 2012 membership data from the ASA where 79.6% of employed members were in the academy.[20]

Education Research in Universities and Research and Development Organizations

As set forth above, universities are the primary employment location for education researchers, including those with faculty positions and those working in university-based research settings. Also, research bureaus, research institutes, R & D organizations, and research agencies in some states or school districts are major sites of employment. The social organization of the work sectors for education research might be viewed as a complex and overlapping set of entities that is largely anchored by faculty in education research doctorate programs[21] but also includes prominent units inside and outside of universities.

Within universities, education research centers vary in size, scope, and purpose. Some are adjacent to and very much reflect the programmatic research interests of specific faculty at an institution. Others are major entities in their own right with quite sizable research teams, projects, and streams of funding involving faculty as well as other education research professions. Examples of long-term prominent centers are the Learning Research and Development Center at the University of Pittsburgh founded in 1963; the University of Wisconsin Center for Education Research founded in 1964; the Center for the Study of Evaluation (now called the National Center for Research on Evaluation, Standards, and Student Testing) at the University of California, Los Angeles founded in 1966; and the Center for the Social Organization of Schools at Johns Hopkins University also founded in 1966. Some of these centers themselves have collaborative partnerships, for example, the Hopkins Center includes a Center for Research on the Education of Students Placed At Risk, which is a partnership with Howard University.

As noted earlier, university-based bureaus appeared early in the twentieth century both as contexts for providing research-based service and research. In 1964, Lazarsfeld and Sieber in their study of organizing education research observed that university units are variously called bureaus, institutes, centers, and laboratories – noting that in some universities

a tension between research and service led to a splitting of the two (Lazarsfeld and Sieber, 1964: p. 37). The Bureau of Educational Research at the University of Illinois, Urbana-Champaign is among the oldest bureaus and is primarily directed to the support of university faculty and students in the development of their research and the identification of funding sources. The Bureau of Educational Research and Field Services at the University of Nebraska, Lincoln in contrast undertakes research and research dissemination in response to requests by the state.

Over the last several decades, an increasing number of research entities on university campuses have adopted a model that establishes a context for structured, long-term collaboration among university researchers, school districts, and community stakeholders. A well-known example of this kind of campus-based education research center is the University of Chicago's Consortium on Chicago School Research, which was established in 1990 and conducts research intended to build the capacity of the Chicago Public Schools to address their most important and pressing challenges.

Beyond the university setting, there are a number of nonprofit research organizations that also have long-standing histories as producers of education research, data, and evaluations. Among the most visible nationally and internationally are the American Institutes for Research (AIR) with a strong emphasis on education research from its founding in 1946 and the Education Program at the Rand Corporation which dates back to the 1970s (Rand was founded in 1948). Some of the most visible companies engaged in educational testing and assessments also have long-term R & D programs. Three notable examples are ETS, the College Board, and ACT. All of these nonuniversity sectors include postdoctoral training and engage graduate students on research teams although, with the exception of Rand, none includes graduate degree conferring programs.

Also private sector organizations include education research units. Publishers like Pearson that have expanded their portfolio to assessment services include R & D units and research teams. Also, state agencies and school districts continue to have research units doing important work. In addition, currently 10 Regional Educational Laboratories (RELs) are federally funded to assist state, school districts, and others to use data and research to improve practices and outcomes.[22] While typically not directly undertaking research, public agencies (e.g., Institute of Education Sciences) and private foundations (e.g., Spencer Foundation) include education research professionals on staff that contribute to the overall capacity of the field. Despite the importance of all of these work sectors, universities and their faculties and research centers are central to knowledge production and to the training of master- and doctoral-level graduates working in these other sectors.

Professional Associations

Education research associations are an important part of the formal infrastructure of the field. As is the case in all scientific and scholarly fields, from their inception, research associations have provided an organizational framework for scholarly interaction, communication, and dissemination. In the early part of the twentieth century, most associations embraced this purpose through convening meetings and publishing journals. In the last quarter of the twentieth century, large national research associations began taking on other programmatic functions that support and advance their fields and professionals within them. Along with new functions came a gradual shift from volunteer-driven organizations to the emergence of an employed staff, although the role, functions, and leadership of elected officers, councils, and committees continue to be central to such associations.

As the largest professional association in education research, AERA evidenced this transformation. The association's functions include the articulation of ethical standards, professional development courses at largely annual meetings, doctoral dissertation and research grant support for early career scholars, initiatives directed to the inclusion of racial and ethnic minorities in the field, and government relations activities to press for research funding and sound R & D policies. While social science societies changed at somewhat different paces, AERA and associations such as the ASA and the American Political Science Association showed similar patterns of development and understandings of their missions by the end of the first decade of the twenty-first century.

With education research being as large a field as it is in the United States, other education research associations evolved and operate to support education research professionals in the field. There are some 24 state and regional education research associations (e.g., Eastern Educational Research Association, California Educational Research Association). In addition, education research within the United States includes research associations in specialized areas such as the Association for the Study of Higher Education, the National Council on Measurement in Education, the History of Education Society, and the Society for Research on Educational Effectiveness. Like AERA, many of these associations include international members. The National Association for Research in Science Teaching explicitly states that it is international. Also, the Comparative and International Education Society has by virtue of its aims an inherently international perspective.

In addition to education research associations, a number of national social science associations (e.g., American Anthropology Association, American Psychological Association, ASA) have well-established subfield specialties in education research with dedicated sections or divisions reflecting this field. These education research-focused subgroups have a strong presence in their respective organizations, and, through the publication of journals (e.g., *Anthropology and Education Quarterly*, *Sociology of Education*) and other activities, they also play an important role in advancing education research as a social science field.

Journals and Knowledge Dissemination

Peer-reviewed journals are the primary mechanism for research dissemination. For the major associations in the United States, journal publishing is a foundational function. As can be seen in Table 2, in the United States, associations

Table 2 Top 100 education and education research journals by year founded, region, and association affiliation

	Year founded				
	Before 1950	*1950–75*	*1976–2000*	*2001–Present*	*All years*

publish the most visible and highly ranked journals. Of the US journals ranked among the top 100 by Thomson Reuters Institute for Scientific Information (TR) in 2012, 68% (34 of 50) were affiliated with research associations. The fact that approximately 70% of the top-ranked US journals founded up through 1975 (18 of 26) were association journals further underscores the early emphasis placed by associations on high-quality publishing, since these journals currently remain highly ranked and cited.[23]

The TR data also provides a window on the overall impact of education research journals. Impact factors for scientific journals are calculated as a ratio of the total number of published items that could be cited to the total number of citations from a journal during a specific period. Figure 1 shows the average impact factors for 2012 and for the 5-year period ending in 2012 for the top 100 ranked journals in education/education research in comparison to other social sciences. These data indicate that the impact of education research journals is comparable to journals in most other social sciences – 1.35 for 2012 and 1.62 over 5 years. As can be seen in Figure 1, the impact of education research journals is much like those in sociology and statistics/probability and higher than in political science and anthropology. Economics and psychology journals have a higher impact than journals in the other social science fields.

International Footprint of Education Research

The international scope of education research as a field of study is long-standing and has broadened substantially in recent years. Table 3 shows national and regional education associations that have been established outside of the United States by founding year. Five associations were established prior to 1960, three in Asia and one each in Europe and South Africa. Between 1960 and 1980 the total number of education research associations more than doubled. In 1970, the World Council of Comparative Education Societies was established. Also, a substantial number of Western European education associations were established in the 1970s.

Table 3 indicates that, during the last two decades of the twentieth century, the growth of education research associations extended to other areas of Asia, Europe, and America. Also, two major international associations – the European Association for Research on Learning and Instruction and the European Educational Research Association – were established in 1989 and 1994, respectively. Since 2000, the global expansion of associations that focus on the advancement of education research as a social scientific field of study has continued. Most prominently, the World Education Research Association was established in 2009. The founding of the Pakistan Association for Research in Education in 2006, the Peruvian Educational Research Association in 2009, and the Slovenian

Educational Research Association in 2011 are further indicators of the ongoing expansion of the field of education research in South Asia, Latin America, and Eastern Europe.

The pattern in the emergence of the top journals in education research also provides an indicator of the international footprint of this field. Table 2 shows the year of establishment of education research journals rated in the top 100 worldwide by TR in 2012. There was an early emergence of these top journals in the United States, with 10 being established before 1950 and comparable numbers of top journals (16) established in each of the last two-quarters of the twentieth century. In contrast, the establishment of what are now top journals outside of the United States occurred later in time (only two before 1950), with 31 of 50 top ranked journals founded in the last quarter of the twentieth century. That the top 100 journals are distributed in equal numbers inside and outside of the United States reflects the global reach of this field.

The proliferation of education research globally is further illustrated in Figure 2 that shows the pattern of growth in the number of citable documents in education research journals in four regions of the world between 1996 and 2012. As noted previously, the impact of an individual journal is measured in part by the total number of published items that could be cited in a given period. Although North America, heavily influenced by contributions from the United States, leads the world in the total number of citable documents published in education journals, Figure 2 shows an overall positive trend in the production of education scholarship across all four world regions. During the first decade of the twenty-first century Asia, North America, and Western Europe showed similar trajectories of growth in the total number of citable documents in education journals. Between 2005 and 2011 the number of citable documents in Latin American education journals also increased. However, in Latin America, both the overall number and the rate of growth in citable documents have consistently fallen below the other regions.

Conclusion

Education research as a field encounters many of the stresses and strains that can beset the social sciences as scientific fields. These sciences are generally not treated comparably to other

Figure 2 Number of citable documents in education journals by region (1996–2012). Source: SJR, SCImago Journal & Country Rank. http://www.scimagojr.com (accessed 05.02.14.).

fields in the natural sciences. The reasons for this status hierarchy are quite complex, but in part may be explained by the fact that social phenomena are often subjects about which laypersons have opinions or perceptions that are strongly held and are not seen to require special training or expertise. The fact that the study of social and behavioral phenomena are not part of elementary or, in the main, secondary school science education reinforces the perception that these fields are lesser sciences (see Levine et al., 2004).

The investment by the US federal government in education research is one indicator of the level of support. As with the social sciences more generally, the federal investment in education research is comparatively low. The overall nondefense budget for research and development in the United States in 2012 was approximately $64 billion (White House Office of Science and Technology, 2013: Table 1). In 2012, the Institute of Education Sciences had a budget of $190 million for research (excluding the regional laboratories) and an additional $110 million for data and statistics through the National Center for Education Statistics (excluding the National Assessment of Educational Progress) (U.S. Department of Education, 2013). The Educational and Human Resources Directorate at the NSF, the primary source of support for education research at the NSF, had a similar budget allocation of $220 million in 2012 (NSF, 2013). Even considering other sources of support at the NSF and the National Institutes of Health, the investment in education research is likely no more than 1% of the total nondefense R & D.

Yet, the study of education throughout the last century and into this century continues to be an arena of pervasive interest. There is wide recognition across countries and cultures of the social and scientific importance of understanding the dynamics underlying education and learning. Education is generally understood to be central to the critical thinking and skills of a population, to a productive and internationally competitive economy, and to a committed citizenry. Even in countries where education may not be universally available or is closed in access to certain segments of a population, leaders recognize that understanding how to educate is an essential function of society.

This pervasive interest can be seen in the social organization of education research as a field and profession and in the quite separable interest in research on education often evident in other fields and disciplines. Just as education is ubiquitous in society so too is education research. Nonetheless, the presence of a dedicated field offers a venue for incremental building of bodies of knowledge, interaction within and across networks of scholars, and a framework for the intergenerational transmission and refinement of methods and substance that would not readily evolve across disparate disciplines or fields.

Education research because of its commitment to an educative process is in many respects a grand discipline within social science research fields (see also Kalantzis and Cope, 2014). Some of the current arenas of inquiry that are capturing the imagination of those engaged education research include open access to knowledge and its effects on the speed with which knowledge is produced and used, education as a measurable societal asset and as a producer of social equality and inequality in society, learning analytics in a world increasingly dominated by digital environments, observational and time-use recording to unravel the teaching and learning exchange, the effects of learning environments (including through the use of technology) on building analytic skills and brain capacity, and the use of information that is produced and available in rapid and real time (known by some as 'big data'). The importance of some of these scientific issues is shaping the emergence or transformation of education research doctorate programs, specialized associations, and journals (e.g., the emergence just in the last decade of learning sciences programs, dedicated associations, and journals).

Part of the measure of any field is its capacity to build and produce useable knowledge, to create opportunities for interaction even where crossovers do not yet exist, and to itself be reflective and capable of change. As emphasized in this article, education research has always been defined and marked by a porous identity. While at times a point of concern and critique, this dynamic portends well for this field as it moves into its second century as a 'work in progress' worldwide.

End Notes

1. During the twentieth century, the field was dominantly called 'educational' research, but 'education' research has become the more contemporary term in the twenty-first century, and thus is used in this article, even when addressing the history of the field.
2. Two examples of areas of methodological contributions that emanated largely from education research are meta-analysis (Glass, 1976) and hierarchical linear modeling (Raudenbush and Bryk, 1985).
3. Both scholarly (Lagemann, 1997; Shulman, 1999) and institutional reports (NRC, 2002) have noted that education research has been critiqued as lacking a 'core' knowledge base and for the absence of consensus on theory and method. Some attribute these critiques to the interdisciplinary nature of the field and the complexity of building a 'distinctive research community' (Lagemann, 1999: 10–11). While observing these challenges, others (Feuer et al., 2002; Levine, 2003; Ranis and Walters, 2004) have emphasized that the strengths and weaknesses of education research are not unique to it or to the social sciences.
4. The reasons why are not clear, although there is considerable conjecture that the continued engagement of academics in training teachers and the low status of the teaching profession may have affected perceptions of education research or distinguishing it from education (Lagemann, 1997, 2000; Labaree, 2003).
5. NADER was not the first education research association in the United States. In 1901, the National Society for the Study of Education (NSSE) was founded to promote scholarly and scientific research on education through convening meetings and publishing a yearbook. NSSE generally held meetings with the National Education Association (NEA), but was not part of NEA. It was dissolved in 2008. See https://nsse-chicago.org.
6. This overview draws upon the history of AERA by Mershon and Schlossman, 2008.
7. Since 2009, the AERA has held an undergraduate conference within the AERA Annual Meeting, with close to 200 applicants for approximately 20 openings.
8. This article focuses on the field of education research and the preparation of research professionals through education research doctorate degrees. Also, graduate schools of education variously offer practice doctorate degrees, but the doctoral training of practitioners is not the focus on this article.
9. During the last quarter of the twentieth century, graduate schools of education increased their attention to offering education research training. In a 1964–65 survey by Sieber and Lazarsfeld (1966) only a small number of graduate schools (less than 30%) emphasized research.
10. The study, An Assessment of Education Research Doctorate Programs, funded by the National Science Foundation (NSF DRL-0836856), is directed by Felice J. Levine and Lorrie A. Shepard, under the auspices of the AERA and the National Academy of Education. Prior studies are few in number. For example, in 1964 Sieber and Lazarsfeld undertook an important set of studies of education research in universities that included doctoral education (see, e.g., Lazarsfeld and Sieber, 1964; Sieber and Lazarsfeld 1966). In 1982 Schneider led a study of doctoral programs in education under the auspices of the then Deans' Network (Schneider, 1987; Schneider et al., 1984).
11. As Levine and Shepard (2008) noted, any empirically based taxonomy will change over time as new areas emerge or others recede in a field. The DocStudy taxonomy is based on the configuration and frequency of the dominant types of education research doctorate programs in 2010.
12. See *Doctorate Recipients from U.S. Universities: 2012* (S&ED, 2012). These data derive from the Survey of Earned Doctorates (SED) based of an enumeration of all individuals receiving a research doctorate from an accredited institution in a given academic year. The SED designates certain fields as education research. The DocStudy (Levine and Shepard, 2008, 2013) offers a more refined classification and estimation. Nevertheless, the SED data provide an aggregate estimate over time that is informative.
13. Table 24 reports on US citizens and permanent residents only.
14. The AERA, for example, has established a programmatic emphasis on research directed to producing knowledge about the field and the education research profession.
15. AERA membership data tables are available from the first author.
16. This estimate is based on the number of doctorates produced in education research annually (2500) adjusted for a 30% attrition (750) of those who do not enter or leave the field over an estimated career span of 30 years.
17. A large number of international members are not international affiliates, but regular or affiliate members or student members. Over the period 2009–13, approximately 15% of AERA members were from locations outside of the United States, with approximately 5% in Canada and 10% in other countries.
18. While, as noted above, there are distinct doctorate education programs within the fields of education research, they share in common being part of an overarching field.
19. For example, 77.2% of political scientists and 82.1% of sociologists who earned doctorates in 2012 were employed in the postsecondary education sector, while only 47.8% of psychologists and 59.4% of economists in the same cohort moved into this sector (S&ED, 2012: Table 61).

20. Membership data were provided by Karen Edwards, ASA Director of Membership and Publications.
21. The number of faculty in such programs was estimated at about 8000 by Levine and Shepard (2008).
22. See http://ies.ed.gov/ncee/edlabs. RELs are operated under contracts with universities (e.g., REL Southeast by Florida State University) and research organizations (REL Midwest by AIR).
23. As Table 2 further indicates, associations outside of the United States do not evidence the same pattern. This pattern may reflect publishers displaying greater interest in establish journals to reach non-US audiences in the last quarter of the twentieth century.

Educational Sociology

Lawrence J Saha, Sociology, College of Arts and Social Sciences, Australian National University, Canberra, ACT, Australia

Abstract

Educational sociology focuses attention on the social factors that both cause and are caused by education. It includes the study of factors relating to education, such as gender, social class, race and ethnicity, and rural–urban residence. Educational sociology has developed a range of sociological theories to explain and guide research into the various levels and types of education, and it has also contributed to the development of methodological and statistical techniques. Three current issues are discussed as examples, namely the relationship between education and social inequality, school violence and bullying, and teacher burnout and the accountability movement.

Introduction

Educational sociology is one of the major subfields in sociology and also in the development and production of educational research and teaching. Because of the enormous breadth and scope of what is called 'education' in modern society, the sociological study of education covers a wide field and is perhaps one of the largest subfields within sociology. As Ballentine and Hammack (2012) point out, education starts with birth and does not end until death. In one form or another, either formal or informal, it takes place throughout one's life. However, sociologists tend to direct their attention to the type of education that takes place in formal institutions which are designated by society to learning in an organized, systematic manner. Thus the sociological study of education, and what is called 'educational sociology,' is generally restricted to education in a formal sense, namely schools, colleges, and universities. Through these institutions, society ensures that a standard body of knowledge, skills, and values get transmitted to future generations.

Emile Durkheim, one of the first sociologists who studied formal education in a systematic manner, argued that formal education is the way that society guarantees its own survival (Saha, 2001). This does not mean that the process of education takes place seamlessly, and that the desired body of knowledge and values do not change, or that it is passed on without contestation. Durkheim himself understood that few societies are in agreement about what knowledge should be passed on through formal education. The divisions within society, such as social class, religion, gender, and race/ethnic groups, usually have some unique preferences about what knowledge should be passed on to the young. As a result, educational policy, particularly in modern multiethnic societies, is usually a source of much disagreement. These disagreements not only mean that much compromise often takes place in the establishment of formal educational systems, but that often two or more different types of schools become established, each passing on at least some unique knowledge and values to those students who attend them. This explains why many modern societies consist of a government school system and one or more private school systems. These are some of the kinds of phenomena that sociologists attempt to understand through their research.

Educational Sociology or Sociology of Education

Two labels have dominated the sociological study of education through its academic development in the English-speaking world. Perhaps the older of the two is 'educational sociology.' Indeed this was the label which was used for the title of the first dedicated journal in the United States, *The Journal of Educational Sociology*. The journal originally was established outside of the official professional academic sociological association, the American Sociological Association (ASA). The journal content reflected the two directions that sociologists took in their study of education. Some were concerned about educational policy and how education 'ought to be' in American society. Others, however, thought that the sociological study of education should be more 'scientific,' and thus more concerned with 'what was actually happening' in educational institutions. However, when a move was made to incorporate the journal into the official publications of the ASA, the members of the latter perspective prevailed, and the name of the journal was changed to *Sociology of Education*. The two labels continue to be used, sometimes interchangeably. For the most part, however, the former tends to be used by sociologists in academic departments of education, while the latter tends to be used in departments of sociology. In the end, both approaches are necessary, as sociologists need to address both the factual and 'scientific' operations of educational systems as well as the policies needed to administer them (Dworkin and Ballantine, 2012). In this article, the labels are used interchangeably.

The sociological study of education experienced rapid growth in the early history of the discipline. All of the 'founding fathers' of sociology, namely Emile Durkheim, Max Weber, and Karl Marx, had something to say about education, although it was Durkheim who was most responsible for establishing the field.

There have been critics of educational sociology throughout its development. For example, some have referred to it as "ivory tower nonsense" (Hansen, 1967) and have noted that it has been characterized by the "sterility of the questions that it asked" (Corwin, 1965). However, more recently it has been considered as "extremely rich, vibrant and diverse" with "an exciting range of substantive issues for investigation, as well as an equally exciting range of theoretical considerations and

methodological tools for undertaking these investigations …" (Noblit and Pink, 1995: p. 27).

But as the field continues to expand into the twenty-first century, better theories and methodological tools are opening the door to more rigorous research. Hallinan, for example, contends that "sociologists of education must conduct theoretically rich research that identifies mechanisms that link exogenous and endogenous factors to student outcomes" (Hallinan, 2011: p. 2).

Theories and Methods in Educational Sociology

Like other areas in sociology, the development of theory and research methods implies a continuing vitality in the field. This has certainly been true for educational sociology. Although the traditional theories emanating from the 'founding fathers' of sociology continue to be important in the study of education, new perspectives continually emerge which identify, clarify, and explain educational phenomena which are unique in an increasingly geographical mobile and technologically sophisticated world population.

Theories

The early classical sociological theories, primarily from Durkheim and Weber, made it clear that formal education, that is schools and universities, played a vital role not only in passing on the social and cultural heritage of society, but also in the maintenance and formation of social inequalities. In the case of Durkheim, these inequalities could be seen as functional insofar as they helped recognize innate talent and motivation among students. For Weber these inequalities which emerged from schooling had more to do with the cultural and political factors which already divided society. Although Marx never developed a coherent theory of education in his critique of capitalism, his ideas eventually led to a very important neo-Marxist educational perspective which focused on education as a form of 'symbolic violence' whereby the social class structure is reproduced through educational processes (Althusser, 1971; Bourdieu and Passeron, 1977). More importantly, this reproduction process has subsequently been found to occur with the corporation and compliance of the students from disadvantaged backgrounds (for example, see Giroux, 1983; Willis, 1977).

These theoretical perspectives focused primarily on the structures, both formal and informal, which divide society. There emerged a completely different (and opposite) theoretical perspective which pointed to micro-level interactions and subjective constructions related to the educational processes. Drawing on seminal work of the early interactionist theorists, such as George Herbert Mead, Charles Horton Cooley, Herbert Blumer, and Irving Goffman, a major sociological perspective was launched by Berger and Luckman (1967), who argued that reality was constructed through people's creative action. In the study of education from a sociological perspective, labeling theory became a major theory which explained educational processes and outcomes in terms of the interactions between all parties involved in the education of young people. For example, teachers and students have expectations of one another's behavior, and these have consequences on one another's behavior. The important work of Rosenthal and Jacobson (1968) has generated a large body of research which has investigated the impact of teacher labeling. However, as Rubie-Davies (2009) has pointed out, the characteristics of the teachers are as important in understanding this process as are the characteristics of the students. Most importantly, however, this rich body of research illustrates the importance of the interactionist perspective for research, which has helped understand educational processes in the classroom. Because these theories focus on the interaction of two or relatively few persons, the body of theories which fall into this category are referred to as micro-theories. Those which focus on organizational structures, or on the major group divisions in society, are referred to as macro-theories.

The sociological study of education has been influenced by many newer and more general theoretical perspectives. Indeed, it can be said that almost every theory in the social sciences has been used to investigate educational processes of one kind or another. These theories often occur in schools or interrelated clusters which are dominated by a particular underlying perspective. For example, in the 1970s a perspective called the 'New Sociology of Education' emerged which shifted the focus from educational student outcomes to the knowledge content of school curricula and who controlled it (Young, 1971). This critical approach provided not only the dual purpose of 'exposing' what really occurred in the structure and process of schooling, but also the liberation and empowerment of those students (and sections of society) who were dominated and disadvantaged by it. This perspective capitalizes on a "critical reflection which liberates or emancipates actors from false beliefs and subsequently leads to concrete proposals for overcoming oppression" (Lakomski, 1997: p. 57). Thus there is not one critical theory, but a range of critical theories, each with its own focal point depending on what aspect of schooling is being examined. These theoretical versions appear in educational sociological subfields such as the curriculum, educational administration, teacher education, educational policy, and planning, to name just a few.

One important critical theoretical perspective is reflected in feminist theories. Feminist theories not only challenge the male bias of most educational research, but they argue that as a consequence of this bias women's experiences in schools are often neglected. Some of these concern the issues of social justice and differential treatment and opportunities in both educational experiences, but more fundamentally the focus has been on educational policies (Arnot and Weiler, 1993).

What is important, however, is that these approaches not only are designed to 'uncover' hidden features of what takes place in schools, but by so doing, they provide the tools to bring about change and reform. These theories stand in contrast to research and explanations emerging from the functional, conflict, and interactional perspectives which attempt to describe and explain educational processes.

A final influential theoretical perspective has influenced many researchers, and it focuses on the wider macro-processes which impact on the increasing expansion of standard organizational and structural schooling models which have rapidly spread, and continue to spread, throughout the world. The institutional and global approach, according to Benevot

(1997), consists of three themes: (1) a focus on the origins and expansion of mass secular systems of schooling throughout the world in the twentieth century; (2) a focus on the institutional aspects of modern education, such as its selection function, its importance in the allocation of social status; and finally (3) the impact of education on other structures and institutions of society, such as gender roles, the nature of work, and even aspects of the nation-state, and the relations between nation-states. Because of the historical and macro-foci of the perspective, it is closely related to theories of globalization.

The spread of mass secular schooling suggests the emergence of a world culture which includes universal models of education systems, and in particular schooling. Meyer (1997) argues that the modern nation-states, and their subsequent educational systems, are shaped by common values relating to education, the nation, and the state. Robertson and Dale (2008), however, argue that these globalizing forces include additional fundamental factors such as international economic competitiveness and an increasingly interconnected global economy. Thus the social and economic values placed on education and mass schooling make this social institution vulnerable to these forces, which in turn are manifested through increasing standardization and accountability measures.

It has been argued that the institutionalization and globalization of schooling impacts not only the structures and processes of school systems, but also the values and expectations of the students within them. Sikora and Saha (2010) argue that the high levels of occupational expectations found across societies, in particular the developing societies, are a reflection of the globalization of the link between education and jobs. Using Programme for International Student Assessment (PISA) data from 50 countries, they found that high levels of occupational expectations were particularly noticeable in the less developed countries. Yet these countries are the recipients of considerable aid through international and nation-state agencies. Ironically, Sikora and Saha argue that this aid might itself be a conduit of the globalizing process which drives the expansion of a standard model of an educational system.

Looked at from a broad perspective, the theories which guide research in educational sociology are broad in their scope, but rich in the insights that they make possible in understanding the many faces of educational systems and the processes which occur within them.

Research Methods

The sociological study of education has always used research methods adopted from mainstream sociological research. However, because of the unique challenges in the study of educational systems and processes, given that students are nested in classes, and in schools, the discipline has also been the center for the development of new research methods, particularly in quantitative data analysis, which have eventually made their way into mainstream sociology. The following section provides an overview of the main characteristics of research methods used in this field.

From the very beginning, the methods used in educational research incorporated both qualitative and quantitative approaches. One only has to examine the methods of the early 'classics' in educational sociology to observe this practice. Early studies of education processes tended to be 'holistic' in nature, such as a study of a school, a particular social group, or education in a particular community, and in which both qualitative and quantitative data were used. This was the case in studies in many countries. For example, Hollingshead's *Elmstown's Youth* (1947) and Coleman's *Adolescent Society* (1961) represent path-breaking sociological studies of American education over 50 years ago, and they are regarded as relevant even today. Similarly, in the UK Hargreaves' *Social Relations in a Secondary School* (1967) and Ford's *Social Class and the Comprehensive School* (1969) used multiple methods in their holistic studies of single schools, and they also produced research which has had long-lasting impact on British educational sociology. In France a classical monograph of this period was Bourdieu and Passeron's *Reproduction in Education, Society and Culture* (1977), which not only introduced the concept of culture capital to sociology, but was also responsible for the development of reproduction theory, which was to become one of the dominant theories in educational sociology. These, and other similar studies in the early years of educational sociology, were to highly influence research for several decades, until the emergence of more sophisticated computer technology and statistical packages made possible the analysis of educational systems and processes in an entirely different manner. But qualitative research methods also continued to develop, but in a very different manner.

In her article of trends in qualitative research in educational sociology, LeCompte (1997) describes how new approaches developed even while the old methods, largely influenced by anthropological and evaluation research, remained frequently used. However, according to LeCompte, what fundamentally changed was a move away from positivistic qualitative studies, based on methods such as observation and other forms of field work, to research based on critical theory and postmodernism. With this shift, the new focus has become the perspective and narratives of the subjects, as the objects of study, rather than that of the researcher. In other words, by focusing on the 'voices' of the subjects of research, the categories and interpretations are those of the teachers and students, for example, rather than those of the researcher. However the assumption is that teachers and students have 'stories' or narratives to tell and to analyze, and the interpretation of their presence or absence becomes problematic. Examples of these kinds of problems are found in studies where the informant is low income and mentally handicapped or where the informants have no 'stories' at all to tell (LeCompte, 1997).

Thus, research based on stories or the life experiences of individuals, and the analysis of narratives and biographies have opened new paths and challenges for qualitative research. According to LeCompte (2009) these shifts in qualitative methodologies can be traced in the series of handbooks of research on teaching produced under the sponsorship of the American Education Research Association from 1963 to 2001. While reflecting a 'sea change' during these years in theory and research in most social science disciplines, new epistemological issues emerged as researchers began to ask 'Whose story is being told?' and whether the researchers have got the stories right (LeCompte, 2009: p. 39). One of the driving forces of

continued attempts to develop qualitative research methods has been desired to avoid a 'top-down' imposition of meanings and understandings of educational phenomena and replace it with new ways of researching which are more "collaborative, participatory, and action-oriented" (p. 41).

While in recent years qualitative research methods have continued to make a valuable contribution to research in educational sociology, so too have the developments in quantitative methods. For a period of time, particularly in the 1980s and 1990s, developments in qualitative methods tended to overshadow those in quantitative research. As LeCompte observed, "Qualitative research was embraced by the educational community with such enthusiasm that in some academic quarters, quantitative research was relegated to the background, caricatured as unable to address real issues concerning real people" (LeCompte, 2009: p. 43).

However, during that period users of quantitative methods were not standing still, and developments in statistical techniques and modeling began to address some of the challenging contexts that educational research presented, namely, how do you study education processes and outcomes of students who are nested in classrooms, sometimes taught by different teachers throughout the day, all within different schools, and across different countries? To further complicate this challenge, quantitative techniques also had to be able to incorporate the educational effects of a myriad of family background characteristics as well as the effects of friendship groups and community contexts. Fortunately, breakthroughs in statistical packages, which emerged in the 1970s, began to reap returns just as qualitative methods were reaching a kind of epistemological endpoint in pushing that research deeper into the conscious world of individual students.

Quantitative research in education is divided into two main groups, depending on whether the research design is experimental or not. Researchers who come through a more psychological or educational psychological tradition tend to favor analyses which involve experimental designs based on a treatment group and a control group. The advantage of this approach is that a single variable can be manipulated in such a way that its causal effect on the outcome can be tested. Researchers from this perspective tend to use analysis of variance, or a variation of it, as their primary statistical tool. This statistical procedure has persisted for generations of researchers, and continues to be popular today.

However, for researchers who take a more sociological approach in the use of quantitative data, the use of survey designs is more typical. The primary difference between experimental and survey designs is that the latter tend to have only one study group, the research participants tend to be larger in number, and there are more variables included in the analysis. However, unlike experimental designs with control and treatment groups, survey designs are multivariate and the isolation of a single causal variable is replaced by multivariate and assumed multicausal models. Nevertheless, the development of new statistical techniques and the increasing frequency of longitudinal survey designs make both the identification of the multicausal effects easier to identify and the disaggregation of the between-student, between-class, between-school, and between-country effects possible. While correlational analysis and multiple regression techniques remain widely used, they are often limited by conditions where demonstrated causality or the disaggregation of effects between levels is less important.

One attempt to solve the problem of multicausality emerged in the 1960s with the development of path analysis. The use of path models was stimulated by an interest in the factors which explained occupational attainments. Following Blau and Duncan's study of occupational attainment among adults in the United States, Sewell and his colleagues at the University of Wisconsin used path analysis to study the attainments of high school graduates who were then followed through university and subsequent occupational careers. What made the work of the so-called Wisconsin model so important for educational sociology was the inclusion of educational variables. For over a decade the use of path analysis to study the determinants of both educational and occupational attainments became dominant among quantitative educational sociologists. Further developments of this approach, using partial least squares (PLSpath) and maximum likelihood techniques (LISREL), made it possible to create a latent variable from a number of observed variables, thus increasing the number of variables and refining their relationships and meanings for path models. However, for the study of school students, there remained the problem of nested data and problems of differentiating between the student, classroom, school, and, in the case of comparative studies, country-level effects.

Major breakthroughs in solving these latter statistical challenges began to occur in the 1980s with the development of hierarchical linear modeling through which the overall ability to explain educational or occupational attainments could be disaggregated into the various nested levels. Further developments which incorporated both path analysis and multilevel modeling have emerged, and procedures such as AMOS, MPLUS, and STREAMS have been developed and are increasingly being used by quantitative educational sociologists, with the result that there have been pressures to collect higher quality educational data which these procedures demand. Overall, these developments have greatly improved the understanding of the complex relationships and multiplex determinants of educational processes and attainments.

Perhaps equally important has been the gradual adoption of these highly sophisticated and complex procedures into mainstream sociological research. Thus advances in the quantitative research into education, to meet unique conditions in educational research, have been of benefit to sociology as a whole. For a more detailed description of the history and development of these procedures, and their importance for educational sociology, see Keeves (1997), Saha and Keeves (2003), and Keeves and Darmawan (2009).

Apart from the above types of research techniques, there are other approaches which have investigated education from a completely different perspective, namely the importance of the interconnection between individuals and the benefits or disadvantages they bring to educational attainments. Network analysis is a growing type of statistical analysis which makes possible the study of the effect of friendship and peer groups among students on educational attainments (Klovdahl, 1994; Saha, 1994). Theoretically, network analysis can be linked with the notion of social capital, a concept which originated in the

work of Coleman, which focuses on the human resources that individuals possess that can be used for various social attainments, including education (Coleman, 1988). For example, Rizzuto et al. (2009) found, in their study of American university students, that the connectivity (network density) of students in a university classroom had a significant, though not the most important, effect on academic performance. In an innovative use of archival data, Eckles and Stradley (2012) found that students who were closely interconnected through residence and classes were more likely to remain at university, compared to those who dropped out, who were less socially connected. These two recent examples illustrate the utility and importance of social network analysis in educational research.

As this exposition has made clear, the theoretical and methodological approaches within educational sociology are varied and diverse. At times this diversity has resulted in conflict within the field. On the other hand, recent discussions of this diversity have seen it as a strength rather than a weakness. For example, Weis and her colleagues, in documenting the struggles between competing theories and methodologies, argue that working across the divisions, rather than maintaining boundaries, will be more productive for the discipline in the long run (Weis et al., 2009).

Some Current Topics in Educational Sociology

As should already be apparent, educational sociology is a broad and inclusive subarea of sociology. Because of the importance of education in society, hardly any aspect of social life is unaffected by it. The topics which are studied and researched are almost endless, ranging from early forms of education through socialization and preschool experiences, through formal educational experiences, both academic and vocational, and finally to forms of lifelong learning which follows the completion of formal educational studies. Furthermore, these educational experiences are often studied in the context of family background characteristics, friendship and peer group experiences, and other similar social contexts. It would be impossible here to summarize issues relating to these topical areas in this brief exposition. Therefore, three current key topics will be examined here to illustrate recent work by educational sociologists. These are education and social inequalities, school violence and bullying, and teacher burnout and the standardized testing and accountability movement.

Education and Social Inequalities

The direct relationship between education and various forms of social inequality has probably been the earliest and most widely theorized and researched topic in educational sociology. The general pattern in all societies is that the more education a person has attained, the greater will be other valued social attainments. But educational attainment is not equally distributed, so that those groups which acquire more education also enjoy more social benefits. The dimensions of these attainment inequalities generally are many, ranging from gender, ethnic and race origins, rural–urban residential locations, government and private school attendance, types of family socialization practices, and social and cognitive disabilities, to name just a few. What has been most striking is that, with the exception of gender inequalities, most of the traditional inequalities have persisted in spite of much research on education and educational reforms. Furthermore, these inequalities exist across societies.

Early theorizing about education and inequality was based on the functional perspective which argued that, because a social role of education is to sift, sort, and allocate the most talented and motivated students into the most important and lucrative social positions, the inequalities are a product of merit, and a sign that the education system is working. The complex process by which this comes about has been labeled the status attainment model. Basically the model assumes that there are many determinants of how much education a person attains, including home background factors, aspirations and expectations, and prior attainments. Then the amount and type of education acquired lead to other occupational and social attainments.

However, because the meritocratic process, studied in this way, always seemed to favor students from privileged backgrounds, countertheories argued that the continued existence of social inequalities in educational systems represented a form of social reproduction which was not merit based, but one based on hegemony, privilege, and power over the education system itself. Starting with Bernstein's research between class-based language codes in England, and their importance in academic achievement (Bernstein, 1971), Bourdieu and Passeron (1977) also found the mechanisms of the reproduction of social class in education in France, not because of a meritocracy but because of the transmission of what he later called 'cultural capital.' Thus the concept of cultural capital, and Coleman's related concept of social capital, provided an alternative explanation for the pervasiveness of social inequality and education.

Empirically, the quantitative studies of the link between education and social inequality found that the relationship existed in most western industrial societies (Erikson and Goldthorpe, 1992), and that class of social origin was a main contributor, although other research found that its effects were diminishing (Dronkers, 1993). Nevertheless the differences between the social classes and education have been found to be persistent across countries (Shavit and Blossfield, 1993).

The direct relationship between education and social inequality has also been found to vary between countries, depending on characteristics of the political and economic systems and also on characteristics of the educational systems. For example, countries with more social democratic systems tend to have lower educational and social inequalities than countries with liberal market economies (Beller and Hout, 2006). Similarly countries which have early selection of students into tracks based on presumed innate ability, or on vocational or academic occupational destinations, compared to countries with nontracked comprehensive education systems, tend to have stronger links between educational attainments and other social attainments (Marks, 2005). Furthermore, it has also been argued that even as the general levels of educational attainment in some societies have appeared to become more equal, for example in the expectation that everyone can attend university and obtain a university degree, there remain hidden factors which bring about negative

and unequal consequences. These emerge when the realistic possibilities among students of attaining goals are not recognized or acknowledged, with the result that failures are worse than if realistic lower level goals were pursued to begin with (Rosenbaum et al., 2011). Thus, ironically, the ideal or perfectionist views about how to reduce or eradicate the link between education and inequality actually have been shown to maintain them, although through hidden processes. Clearly much sociological research remains to be done, and policies need to be developed, at both the school and the political and economic level to reduce the link between education and social inequality, if that is, indeed, the goal of a society.

School Violence and Bullying

Recent years have seen a rapid increase in various forms of violence taking place in schools in many countries of the world. Because schools serve young children and teenage youth, they are seen as places that should be free and safe from various forms of psychological and physical harm. Apart from the disruption that these harmful forms of behavior cause to the teaching and learning process, school students are extremely vulnerable and powerless to protect themselves when confronted with them. Similarly, it has been demonstrated that teachers suffer negative consequences, such as burnout, when they are made to work in an unsafe and threatening school environment. Therefore, sociologists, parents, and education administrators and policymakers have contributed much to our understanding of the factors which contribute to unsafe schools.

Violence in schools can take many forms, ranging from the 1999 shooting at Columbine High School in the United States to physical and emotional abuse between students. While the Columbine High School incident may have been the result of individuals with social and emotional problems, the frequency and diversity of incidents such as these, not only in the United States but elsewhere, poses important sociological research challenges and subsequent policies. For example, the experience of violence among youth generally, whether domestic or in the school, can have disruptive consequences for academic performance among students, as well as their relationships with other, and their own psychological well-being (Huang and Mossige, 2012).

Bullying, in particular, has attracted considerable research attention from both sociologists and psychologists. Although school bullying had been regarded by many as a normal part of school life, ever since the seminal and influential work of Olweus, who began to study bullying in 1970 in Scandinavia, it has become regarded as an important social problem in schools. Olweus' research has focused on both the bully and the victim, and takes into account both psychological and sociological factors (Olweus, 1993). Recent researchers on bullying have also included both sets of variables. For example Cassidy (2009), in his study of adolescent youth in the United Kingdom, found that bully victims were more likely to be girls, were more likely to come from less supportive families, and were more likely to have a lower group identity and to be poorer in problem-solving skills. Bibou-Nakou et al. (2012), who studied Greek secondary school students using a qualitative approach, found that the students themselves thought the school was partly responsible because of the competitive environment it fostered. Thus programs directed at lowering or eliminating the incidence of bullying in schools, such as that put forward in Norway, include primarily sociological variables, such as the promotion of more empathetic relationships between students and strong leadership by the teachers in fostering a more cooperative and an antibullying environment (Roland et al., 2010).

Bullying continues to be considered a serious issue in educational systems throughout the world. Rigby and Smith (2011) argue that, overall, the incidence of bullying has declined, largely because of the various intervention programs which have been put into place to reduce or prevent it. However, because of the growing dominance of electronic technology, new forms of bullying, such as outside-of-school cyber bullying, appear to be replacing the traditional in-school bullying. Research into both in-school and out-of-school bullying continues to expand our knowledge of the causes and consequences of this type of violence among youth. Sociological research has made considerable contribution to the better understanding of bullying in schools, and how to treat and prevent it.

The Accountability Movement and Teacher Burnout

The teacher counterpart to the consequences of bullying among students is teacher burnout. Teachers play a crucial role in educational processes, but at the same time they are caught between a number of conflicting pressures, in particular those relating to the expectations of parents, the indifference or even the hostility of students, and the authoritarianism or unsupportive posture of school principals and other administrators. The teacher has been the object of study virtually since the beginning of the sociological study of education itself, beginning with Durkheim's study of education, especially what he called 'moral education.' Durkheim contended that a fundamental purpose of education was to form children into adults who were fully integrated into society and its norms. For him, the teacher played a central role in this process, especially in providing discipline, integration into social groups, and the gradual development of autonomy (Durkheim, 1961(1925)). Two important early sociological works on teachers were Waller's *Sociology of Teaching* (1932) and Lortie's *Schoolteacher: A Sociological Study* (1975).

Lortie (1975) foreshadowed some of the current problems facing the teaching profession and teachers when he observed that teachers, at least in America, were 'both honored and disdained,' partly because they are deemed to be professionals, but at the same time are paid relatively low wages (p. 10). According to him, they occupy a 'shadowed social standing.' This insight seems to have been predictive of many of the pressures on teachers today in light of their loss of autonomy and professional status, and their increasing subjection to accountability policies about which they have little control. These kinds of pressures have produced what contemporary sociologists and psychologists call 'burnout.'

Although psychologists consider burnout to be primarily a problem internal to the individual, sociologists see it as a product of a work environment which removes the meaning and power from the teacher. Thus Dworkin (1987) has argued for a sociological approach to the study of teacher burnout

which focuses more on the organizational structure of schools and the relationship between teachers and school administrators rather than with students and parents. Thus, rather than focus on the psychological characteristics of the teachers, a sociological approach would focus on aspects of the school, and in particular the administrative style of the principal and other aspects of the relationships between the teachers themselves. Indeed, Dworkin et al. (2003) found that teachers in schools with a more democratic environment and more teacher autonomy were less likely to experience burnout symptoms.

In contrast to the above, one feature of the current globalization process is the increase in the use of standardized testing of students to assess not only the students' performance, but also that of teachers and principals. As Natriello (2009) points out, there are negative consequences for teachers with the introduction of standard testing, with costs to teachers for the low performance of students, thus the name 'high stakes testing.' The introduction of this form of standards-based policy is part of an increasing global movement which is removing teacher professional autonomy and reducing the profession to that of perfunctory bureaucratic personnel in the system. Sociologists who study education are increasingly turning their attention to the changing nature of the teacher profession under these new organizational circumstances.

Conclusion

The sociological study of education is a broad-ranging part of the educational and sociology disciplines. Because of the pervasive nature of education into all sectors of the lives of individuals, and also into the functioning of society as a whole, the discipline is extremely inclusive and there is hardly a sector of society where it is not relevant. Educational sociology has changed extensively since Emile Durkheim began to lecture about it to his students at the Sorbonne. But just as during the early days of sociology, so too today the study of education from a sociological perspective addresses important contemporary issues across societies. Some of these issues are common to all societies, such as those relating to inequality, while others are more unique to the characteristics of individual societies, for example issues relating to social and economic development. Educational sociology occupies a central place in the disciplines of education and sociology. In terms of both theory and research methods, it has made important contributions to the studies of education and also to wider fields of sociological research generally.

Educational Systems: North America

Gerald K LeTendre, The Pennsylvania State University, University Park, PA, USA

Abstract

Education in North America, since colonial times, has been shaped by a cultural dynamic that promotes education as an essential good that is constantly being expanded while also seeing education as potentially disruptive, subversive, and decisive – hence something that must be controlled and regulated. The national systems of public, compulsory education in Canada and the USA have been largely shaped by this cultural dynamic with some differences in historical and cultural forces. In this article, shared cultural dynamics are discussed and an overview of other subsystems of education, such as military schools, tribal and historically black colleges, and religious schools, is provided.

North America is home to two national systems of public, compulsory education that differ in size, degree of centralization, and organizational structure but have been shaped by similar historical and cultural forces. In this article, shared cultural dynamics are discussed and an overview of other subsystems of education, such as military schools, tribal and historically black colleges, and religious schools, is provided.

The Effect of Religion and Language on Early Forms of Schooling

Early in the seventeenth century, Father Superior Paul Le Jeune sat down with 'a small Indian boy on one side and a small negro on the other' and attempted to instruct the children in the Catholic faith. While brief and ineffective, 'as neither of the three understood the language of the others,' Le Jeune's efforts epitomize the tenor and focus of schooling in North America during the seventeenth and eighteenth centuries (Parkman, 1983: p. 413). This early encounter is also a good example of the cultural dynamic that persists to this day: education continues to be offered to an ever-expanding set of people, but groups battle for who will control the content and access to various types of education.

In both the French and English colonies, schools were used to maintain existing social hierarchies and assimilate non-European populations by disseminating religious views, inculcating moral virtues (European), and instilling literacy (in English). Early colleges (e.g., the Jesuit College in Quebec or Harvard College) provided instruction in religious dogma and the Christian sacral languages. Literacy was tied to religious indoctrination, and the bible was probably the most common school 'text' (see Kett, 1977 or Sutton, 1988). As Cremin noted: "During the first phases of the Virginia settlement, for example, education was in the hands of the ministers, who used it both as an instrument for promoting discipline and order among the colonists and as a device for winning the loyalty of the natives" (Cremin, 1970: p. 9).

The impact of schooling was limited, though, because during the seventeenth, eighteenth, and early nineteenth centuries most of the population received little if any formal education. There were early attempts at vocational (or domestic) education – for example, the Ursuline nuns of Montreal received "a thousand francs to buy wool, and a thousand more for teaching girls to knit" (Parkman, 1983; Cremin, 1970: p. 1357), but most 'education' consisted of skills learned in the family or apprenticeships. Even slaves participated in these forms to a wide extent: O. Equiano notes that he was trained as a ship's pilot as a slave (Equiano, 1995: p. ix). Education in the colonies was unsystematic, polymorphous, and above all, practical.

Emerging Systems: Education to Transform Society

In the USA, networks of public schools developed rapidly in the early 1800s. Early architects of the public education system, such as Thomas Jefferson, believed that a secular, public system of schools would serve as the foundation of democracy in the new republic. Benjamin Rush lobbied (albeit unsuccessfully) to create a state-funded system of education in the state of Pennsylvania. Horace Mann worked tirelessly in the cause of the 'common school' in Massachusetts and worked to establish 'normal schools' to train teachers – a group whose educational accomplishments were often astonishingly meager in the 1800s.

Driving these movements for educational reform was a widespread belief in the transformative power of education and a desire to build a system of education that would change society – a cultural tendency that has been piquantly labeled as a propensity to 'tinker toward utopia' (Tyack and Cuban, 1995). Rush was one of the first to articulate these ideas in a systematic way. He noted: "Our schools of learning … will render the mass of people more homogenous, and thereby fit them more easily for uniform and peaceable government." Enumerating "a few advantages of learning upon mankind," he wrote "A free government can only exist in an equal diffusion of literature … and where learning is confined to a *few* people, we always find monarchy, aristocracy and slavery" (Rush, 1787: pp. 1–2, 14).

Yet, during this same period, many state legislatures began to systematically prohibit literacy and other forms of schooling to both slave and free African populations by denying them access to education. "By 1835, every southern stat had a law prohibiting the schooling of slaves" (Smith, 1984: p. 688). During the same period that industrial education experiments

for white, working-class girls were occurring in northern towns like Lowell, Massachusetts, education for African-Americans saw a brief flowering after the Civil War (1870–80) that was suppressed by the institution of segregated schools.

It was not until the late 1800s that educational progressive like the philosopher John Dewey gained widespread political ascendancy and began to 'tinker' with public schools in order to transform the social order. From the late 1800s through the end of the Second World War, scholars and politicians from a wide range of backgrounds worked to extend and systematize public schooling. Yet these reformers typically assumed, as did Rush, that schooling would homogenize new waves of immigrants and make them 'good citizens' of Canada or the US.

Conflict of Ideals: Maintaining Society or Transforming It through Schooling?

The historical development of the North American school systems was affected by conflicting ideals about what schools should do for society. One end of the continuum is the view that school should be a vehicle for instilling morals, proper behavior, and transmitting a stable social order. At the other is the view that schools should allow students the widest range of self-determination and exploration and eliminate old prejudices, thereby paving the way for a new, and better, social order.

Colonization, Native Peoples, and Schooling

Early in the development of both the US and Canadian systems of education, special schools were created for the children of Native or First Peoples that stripped them of their culture and language and attempted to replace them with English, European moral sensibilities, and 'Christian' virtue. These subsystems of education, including Bureau of Indian Affairs schools in the USA and church-run boarding schools in Canada, continued to function in this manner well into the twentieth century. At the start of the twenty-first century, some groups in Canada are still pursuing legal action against such schools for the abusive treatment of children. And from the 1960s on, there has been considerable educational reform among Native communities, including the development of a system of tribal colleges in the US.

From Segregation to *a Nation at Risk*: The Federal Role in US Public Schools

In the former Confederate States of the US, freed slaves made significant educational advances during reconstruction until 1873, when the political imposition of Jim Crow laws and subsequent legalized segregation (flowing from the Supreme Court decision of Plessy vs Ferguson, 1896) reversed the educational advancement of many African-Americans. A small, but influential, number of students enrolled in historically black colleges and universities which continue to play a significant role in the USA today (Drewry, 2003). Beginning with the early Civil Rights movement in the US, renewed political battles occurred over the role of the nation's schools. The US Supreme Court decision of Brown versus the Board of Education (1954) overturned the legal support for school segregation, fomenting widespread social unrest and unprecedented school reform. In one of the few instances where federal troops have been used to countermand the orders of state leaders, National Guardsmen opened a high school in Birmingham, Alabama and allowed a handful of black teenagers to enter.

The US federal role in public elementary and secondary schools has continued to grow, and has increasingly become the focus of intense political conflict. Events such as the launch of the Russian satellite Sputnik and the publication of *A Nation at Risk* set off tremendous public debate about how schools were failing children and what could be done about it. While many have interpreted school reform since 1980 as an 'attack on the public schools,' attempts to create charter schools, provide vouchers for parents to send children to private schools, or pass laws making home schooling easier are evidence of a continued belief that education is the best tool for creating a better society.

Achieving Equity: Conflict over Language, Religion, and the Curriculum

A concern with educational equity has dominated educational concerns since the 1960s but the focus has shifted from assuring equal access to ethnic or racial minorities to one of who ultimately controls what values the school will transmit. These battles – over language, the teaching of religion (e.g., offering Creation Science), and general course content – have been far more vociferous in the US than in Canada. In the US constitution, there is no clear enumeration of educational rights comparable to that found in the Canadian Charter of Rights and Freedoms which specifically details the educational rights of language minority parents. This leaves open the possibility of political referendums, like the California Act ending bilingual education, to substantially change the focus of schooling.

The Systems Today

Despite the progress made in establishing comprehensive, egalitarian systems of public education through the secondary level, the public school systems in the US and Canada have not yet been able to fully rectify persistent problems of social inequality and conflicting cultural values. Yet the history of tension and educational experimentation has resulted in highly decentralized systems of free, public education often emulated by other industrialized nations. In the Canadian system, under the British North America Act of 1867, provinces have wide discretion in setting educational policy, and there is no national ministry of education. In the US, individual states have broad powers to set educational standards but locally elected school boards exert considerable control on the day-to-day operation of the schools. Federal control over schools in the US is indirect, typically using laws that require states to meet certain standards in schools in order to obtain federal funds for education to insure compliance.

In both nations education is compulsory from about ages 6 or 7 to about age 16. In Canada, students make the transition from elementary to secondary schooling between sixth and eighth grade (with a slightly different system in Quebec). In the

US, despite the highly successful junior high school movement of the early twentieth century, there is no standard form of early secondary school organization. About 75% of students in the USA graduate on time from public high schools (Chapman et al., 2010: p. 52), compared with about 84% of Canadian students (http://www.statcan.gc.ca). Although dropout rates have been falling in both countries, these statistics obscure the fact that minority students have statistically significant lower mean achievement scores, higher dropout rates, and lower rates of college enrollment than majority students do.

The cultural emphasis on public school as the means of promoting social change or maintaining a peaceful and orderly society has often led scholars to ignore other nationwide systems of education. In any broad assessment of systems of education in North America, the role of tertiary education, military schools, and religious schools must be addressed.

The Tertiary Sector: Dominance in the World System

At the university level, in the US, and to some extent Canadian, the cultural oppositions that affect elementary and secondary education have largely disappeared. If we compare two institutions that have had a profound impact on the development of college education in general – Harvard University and the University of Virginia – we find two distinct historical roles. For much of its history, Harvard educated the New England social elite and the Protestant clergy. The University of Virginia, while also transmitting social privilege, had a secular orientation that was replicated in the land-grant colleges set up around the US. Although land-grant colleges were sometimes modeled on elite private colleges (e.g., the University of Georgia and Yale University), these institutions focused on improving the conditions of the state populace and offered courses in such pedestrian subjects as agricultural or domestic science. Enrollment grew rapidly; most states now boast a network of high-quality public colleges or universities accessible to a large segment of the populace.

Over time the differences between highly ranked private and public universities have declined, giving rise to the 'research university' that combines undergraduate training with advanced research in virtually every discipline currently studied. Many US and Canadian universities have eclipsed the European institutions on which they were originally modeled as international centers of knowledge production, and the US is widely recognized as the world leader in production of PhD recipients.

Military Schools and Education

Over half of high school graduates go on to some form of college in the US and Canada, but a large percentage of the population still uses the military as a means for educational advancement. For children of working-class families, military training and military service offer low-cost educational opportunities. Not only does the military provide basic instruction to its enlisted men and women, in both nations it also runs an independent system of elementary and secondary schools for the children of military personnel.

The US military also has a substantial tertiary presence. It operates highly regarded military colleges such as the Army Academy at West Point and funds students in public and private colleges through the officer training (i.e., the Reserve Officer Training Corps). Less visible, but not less important to tertiary education, the US Department of Defense funds extensive research projects, providing substantial external sources of revenues for many colleges.

Religious Schools and Churches

Churches and religious schools form another diverse system outside of public schooling. "As in colonial times, the churches continued to serve as centers of formal and informal education" (Cremin, 1970: p. 383). The role of churches as centers for disseminating education and promoting social change was dramatically seen in the US, when in the 1960s, Sunday sermons melded into political calls for ending segregation. At present, US and Canadian churches are host to a wide array of meetings that have an explicitly educational component. Large suburban churches typically offer a range of weekly classes and meetings ranging from independent piano lessons to church-sanctioned marriage classes. These activities are distinct from, and constitute a considerable educational impact over and beyond, the activities of private (US) or state-related (Canada) religious schools.

Religious schools (primarily, but not exclusively Christian) are found throughout North America, ranging from local kindergarten programs on up to world-class universities like Notre Dame. Both nations experienced considerable political conflict over the role government should play in supporting these schools. In the US political battles and court challenges (such as the conflict in the 1840s regarding Catholic schools) have generally been resolved to reinforce the separation of church and state, although groups like the Amish have mounted successful court challenges that have limited the state's ability to enforce compulsory schooling laws. In Canada many school boards were organized along denominational lines, and there is considerable variation in the relationship between provincial educational authorities and church-supported schools.

Experimentation and Innovation: The North American Educational Dynamic

Mr. Fredrick Douglas, a former slave, penned one of the most compelling statements of North American beliefs in the transformative power of education. Douglas wrote:

> Mr. Auld [his owner] … at once forbade Mrs. Auld to instruct me further, telling her, … that it was unlawful, as well as unsafe, to teach a slave to read. The very decided manner with which he spoke, … served to convince me that he was deeply sensible of the truths he was uttering … and the argument which he so warmly urged, against my learning to read, only served to inspire me with a desire and determination to learn.

> Huggins, 1980: pp. 42–43

The focus on who shall be educated has shifted to higher education as attendance through secondary schooling became standardized. Jerome Karabel (2005) showed the desperate

lengths that administrators at some Ivy League schools went to in order to prevent immigrant, Jewish, and working-class children from entering. The end of the twentieth century saw repeated legal challenges to affirmative action and other forms of race-conscious admissions policies, despite strong evidence that these programs were effective in opening access to more students (Bowen et al., 1998).

North Americans share a culture that places extreme emphasis on the power of education to transform both the individual and society and typically view schools as important institutions of social change or control. However, there is considerable cultural conflict over how schools are to be used: many citizens hold the view that a good government should mandate a system of free and comprehensive public education that is uniform for all, while others view any government intrusion into educational matters with extreme aversion. This dynamic is currently expressed in concerns about universities becoming too much like corporations (Bok, 2004) and whether colleges actually educate students in ways that lead them to useful occupations (Arum and Roksa, 2010).

North Americans also share a cultural tendency to engage each new educational innovation as a chance to move one step forward toward social utopia. This is true for groups that have long faced social oppression and bans on schooling. For example, having endured the 'cultural genocide' promulgated in schools like the Carlisle Indian Industrial School, many US Indian nations have launched their own tribal colleges, and organized the American Indian Higher Education Consortium. This facet of North American culture may appear to others in the world as an obsession with educational reform, yet, this cultural dynamic has served to create a system of public education that is widely emulated. In the 1980s and 1990s, the performance of US and Canadian students on international tests of academic achievement caused many to declare the failure of North American schools and praise the educational culture of East Asia. Few saw the irony of the situation: the Japanese school system was heavily influenced by educational reformers of US and educational policy makers in East Asia continue to look to North America as a center of educational reform and research.

Educational reform initiatives originating in North America will continue to influence educational systems around the globe. Looking toward the future, the most significant changes in systems of education will be wrought by the historical confluence of new electronic communication networks and a resurgence of political efforts to decentralize the control of schools. This can be seen in both the home schooling and charter school movements.

Widespread access to immense databases and electronic communication now allows parents to provide children with access to a world-class curriculum within the home, thereby weakening old claims that 'home learning' is greatly inferior to 'schooling.' While the majority of home-educated children belong to fundamentalist, Christian groups, a wide range of parents, anywhere from 300 000 to over half a million around 1995, now opt to school their children at home (U.S. Department of Education, 2000).

Charter schools, in the US, have also increased in the wake of the educational restructuring movement of the 1980s and 1990s. These schools are publicly funded and subject to governmental regulation but operate under fewer restrictions than ordinary public schools. There is great variation in state laws regarding the establishment of these schools, and only a small percentage of the US school-age population attends charter schools. But again, the ability of a small number of adults to access an immense amount of literature, music, and art computer-based networks has made the establishment of such schools quite viable.

The demand for these, and other alternatives to public education, will continue to arise from the important cultural role that education has in North American society. The early part of the twentieth century saw the dramatic expansion of an organized public school system, then viewed as the best way to move society forward. The early part of the twenty-first century will likely see dramatic decentralization as families push for more autonomy over their child's education and individuals of all ages continue to resist any attempt to control what they can, or cannot, learn.

Abstract

Since Campbell et al. (1954) first defined political efficacy, numerous studies emerged placing emphasis on: (1) the theoretical relevance of the concept for the functioning of liberal democracies; (2) its relationship with other political attitudes and behaviors, and (3) the (unresolved) controversy around its measurement. *This article provides a comprehensive* overview of the nature and evolution of the literature on political efficacy by presenting how disciplines such as political science, sociology, communication and media studies and psychology *tackle these questions.*

Political efficacy is defined by Campbell et al. as "the feeling that individual political action does have, or can have, an impact upon the political process, i.e., that it is worthwhile to perform one's civic duties" (1954: 187). It is an important prerequisite for the conventional forms of political participation – voting and membership in party and civic organizations – viewed as vital for maintaining functioning and stable democratic societies. Debates over the definition of political efficacy, its measurement on standard surveys, its cross-national and cross-temporal comparability, and its causes and effects fill numerous pages of scholarly journals and monographs.

The Concept of Political Efficacy

In early quantitative studies, measures of political efficacy are used to separate those who believe "the affairs of government can be understood and influenced by individual citizens" from those who believe "politics is a distant and complex realm that is beyond the power of the common citizen to affect" (Campbell et al., 1960: 104). Early empirical work treats political efficacy as a single concept and errs toward tapping an individual's belief about their own ability to be effective citizens in the public sphere (Pateman, 1970; Thompson, 1970; Finkel, 1985). Citizens who have such abilities are seen as possessing what Almond and Verba (1963: 257) call "subjective competence," and their presence is vital to the stability and functioning of representative democracies.

However, significant scholarly disagreement exists, even in the early literature. As an example, Muller (1970) argues that Almond and Verba's concept of political competence really has three dimensions: (1) the attention one pays to politics and public affairs as measured by following the news, knowledge of political leaders, etc.; (2) the ability to influence government or a belief that one would get involved in a civic matter and be effective at affecting change; and (3) political efficacy which contains measures tapping citizen beliefs as to how responsive they believe the government is to their concerns.

Rosenberg's (1954–55) qualitative work from the early 1950s identifies respondents reluctant to discuss politics because of their feelings of inadequate expertise or knowledge of the subject. These individuals are both lacking in political awareness and do not have faith in their ability to participate. Other respondents are shown to disengage from politics because of feelings that it is 'futile' to participate because the political class is seen to be unresponsive to the beliefs of ordinary citizens. Many who feel inadequate also feel the system is unresponsive, but there is also a group of interviewees who, regardless of their own agency, feel that politicians and the system will never be responsive. This differentiation is picked up by Robert Lane (1959: 149) who notes that political efficacy "combines the image of the self and the image of democratic government. [It] contains the tacit implication that the image of the self as effective is intimately related to the image of democratic government as responsive to the people." Beliefs that politicians are responsive to the needs of ordinary citizens is dubbed external political efficacy, and peoples' subjective assessments of their abilities to affect political change is coined internal political efficacy.

There is an expectation of interplay between citizen levels of internal and external efficacy, so even though the concepts are viewed as theoretically distinct, high levels of correlation between the two types of efficacy are expected (Clarke et al., 2010). Coleman and Davis (1976: 191–193) summarize: "[I]ndividuals who believe the system is responsive to people like themselves will be more likely to believe that they personally have the skills to induce government officials to act" (quoted in Craig and Maggiotto, 1982: 86).

Research from the 1980s brings questions about construct and statistical conclusion validity as it relates to the concept of political efficacy. Balch (1974) empirically demonstrates that survey questions measuring efficacy break down into two separate dimensions. Craig and Maggiotto (1982) argue that high levels of correlation between the efficacy dimensions should not be assumed because internal efficacy is a measure of internal 'political effectiveness' while external efficacy has more to do with attitudes toward 'system responsiveness.' According to Craig et al. (1990: 305), the correlation that does exist occurs "presumably because beliefs about one's own competence help to shape beliefs about the potential for citizens generally to play a meaningful role in political decision making." But there is a counterargument. Research dating back to the early 1960s (e.g., Agger et al., 1961) suggests that those low in internal efficacy can be more likely to believe that politicians are doing what they can to help the citizenry. In contrast, those high in

internal efficacy believe that they will do a better job in office than those elected and this mentality is reflective of or fosters low levels of external efficacy. The fact that internal and external efficacy can, in some circumstances, be mutually reinforcing while in others is unrelated underscores the need to divide the concept of efficacy into two. After decades of research, scholars agree that internal efficacy concerns "citizens' feelings of personal competence to understand and to participate effectively in politics" (Craig et al., 1990: 290) while external efficacy focuses on citizens' perceptions of the responsiveness of political bodies and actors to citizens' demands (Balch, 1974; Converse, 1972; Miller et al., 1980).

Pollock, III (1983) and Zimmerman (1989) break people into one of four groups depending on their internal and external efficacy levels. Group 1, those with low levels of internal and external political efficacy, eschew all forms of political participation, and are seen as 'uninvolved.' Those in group 2, who do not feel personally competent enough to participate in politics but feel the system is responsive to their needs, are more likely than those in the first group to vote or participate in a campaign but just as unlikely to protest or be active in political groups. Those in this group are happy to follow, for the most part leaving politicians alone as group members lack confidence in their own expertise to play a more active role in politics. Group 3 contains individuals with high levels of both internal and external efficacy. They are far more likely than those in group 1 to vote, campaign, contact others to discuss politics, and be members of groups. Zimmerman (1989) also notes that this is the group most likely to produce future politicians. Finally, those in the last group, who have high levels of internal but low levels of external efficacy, are more likely than those in the other groups to participate in protest activity and almost as likely as respondents in Group 3 to participate in a campaign or contact people to talk politics. However, Group 4 respondents are reluctant to vote or join conventional political groups.

The Relevance of Political Efficacy

The conceptualization of political efficacy is of paramount salience due to its implications for political disengagement and participation in liberal representative democracies. (Examples of literature include: Almond and Verba, 1963; Balch, 1974; Barnes, 1966; Barnes and Kaase, 1979; Campbell et al., 1960; Craig and Maggiotto, 1982; Craig et al., 1990; Easton and Dennis, 1967; Gamson, 1968; Niemi et al., 1991; Rosentstone and Hansen, 1993; Smetko and Valkenburg, 1998; Siegelman and Feldman, 1983.) Scholars consider subjective or internal political efficacy to be an essential indicator of the health of democratic regimes since sentiments of system legitimacy underlie feelings of efficacy (Finifter, 1970; Pateman, 1970; Smetko and Valkenburg, 1998), and high levels of political efficacy are a potential defense against citizen disillusionment with democratic structures of governance (Easton and Dennis, 1967). Citizens in democracies theoretically have higher levels of external political efficacy than those living in authoritarian or dictatorial regimes because of the sense that representative governments are attentive to their needs. This responsiveness facilitates citizen attentiveness and interest in politics and personal political empowerment, which, in turn increases internal efficacy. In semi-authoritarian and dictatorial regimes, this link is severed, partially because of the state's ability to curry favor with chosen groups rather than via the democratic process (Coleman and Davis, 1976).

Psychologists who study individuals' feelings of personal self-worth and efficacy note that people usually undertake collective action or join group activities only when they believe their participation is effective in producing outcomes they support (Bandura, 1995). Participation in politics is predicated on the belief that citizens can affect change and/or politicians and public officials are responsive to their participatory actions. Citizens' sense of political efficacy is highly correlated with the decision to turn out to vote (Campbell et al., 1960; Clarke et al., 2004) and become active in political parties (Whiteley, 2011). Declines in turnout over time are linked to falling levels of external political efficacy because a lack of perceived governmental responsiveness to people's problems reduces the belief that participation is a useful activity (Abramson and Aldrich, 1982).

Internal and external efficacy positively correlates with voting behavior in panel studies of political participation, but external efficacy is a stronger predictor of more high intensity participation such as attending campaign events or donating to political causes (Finkel, 1985). In a study of the Canadian public, Clarke et al. (2010) find that political trust has a strong correlation with efficacy and note that both internal and external efficacy are strongly related to the levels of satisfaction with democracy and the influence people believe they have on politics. In contrast to the findings of Finkel (1985), they find that most forms of political participation such as voting, the decision to contact elected officials, and boycotting and petitioning government actions have a stronger relationship with internal than with external efficacy. This can arise because political interest manifests itself into structured discussions and deliberations over political matters that can in turn improve internal political efficacy, although the relationship may be indirect (Morrell, 2005). When discussion about politics arises, more high intensity forms of political action follow.

The concept of political trust, defined by Arthur Miller (1974) as the citizen's belief that the government and politicians are "producing outputs in accord in accord with individual expectations" often appears with political efficacy as a co-determinant of political action. Gamson (1968) notes that participation in mainstream political participation requires *both* high levels of efficacy and trust, and those lacking in trust, often labeled as 'politically cynical,' but high on levels of efficacy are prone to mobilization for protest activity. In contrast, those lacking both trust and efficacy are apathetic but unlikely to do anything to ameliorate their situation. Finally, those trusting but lacking in efficacy are willing to see the system continue to function without their active involvement.

Seligson's (1980) study of peasants in Costa Rica suggests that high levels of political cynicism or distrust is more strongly related than efficacy at predicting anti-systemic political activity while efficacy is a stronger predictor than trust at predicting the more standard forms of political participation, but the evidence is mixed (cf Pierce and Converse, 1989). Standard forms of political participation among the distrusting but politically efficacious is possible if education levels are high (Chan, 1997)

and potential voters believe are trustworthy opposition candidates waiting in the wings (Nilson and Nilson, 1980). (For an overview, see also Levi and Stoker (2000).)

A disconnect between levels of trust and efficacy are not the only potential drivers of unconventional participation. Converse (1972) notes a decline in political efficacy during the 1960s, a point that, in light of increasing levels of education in the (American) population is surprising to scholars. However, a clear picture emerges when distinguishing between the internal and external components of efficacy – during times of political upheaval, efficacy gaps may emerge. Many citizens of the late 1960s and early 1970s possess high levels of internal efficacy but come to believe politicians and the system is unresponsive to their demands. The unconventional forms of political participation seen in the United States during the 1960s and 1970s are a function of high internal efficacy and low external efficacy (Craig, 1980).

The Antecedents of Political Efficacy

Perhaps the best-known finding concerning differences in efficacy levels among citizens within a nation concerns the link between political efficacy and education. Agger et al. (1961) notes that the completion of a course of higher education is strongly and positively associated with an individual's propensity to believe they are politically efficacious. Prewitt (1968: 226 as cited in Aberbach, 1977) argues that education may be the key contributor to higher levels of political participation. Studies of community action in the late 1960s action posit that low status groups and racial minorities may not effectively organize because of their low levels of education and empowerment (Lipsky, 1968). Children in deprived environments are noted to exhibit higher degrees of hostility toward the political system and politicians and lag behind wealthier students in their levels of efficacy (Lyons, 1970). Recent findings (e.g., Gimpel et al., 2003) describe how African-American youth continue to lag behind both white children and Asians when it comes to their levels of both internal and external efficacy.

Education is seen as so vital to the development of political efficacy that political scientists place emphasis on determining what makes young people efficacious and interventions are designed to raise levels of political efficacy via school curricula or civics education (e.g., Langton and Jennings, 1968). The idea is that increased civics courses increase political efficacy, which is positively related to political interest and the propensity to participate in political discussions, both important precursors for emerging democratic citizens. Although education is the main driver of efficacy and a child's political development, cross-cultural studies show that other social demographic factors are also related to higher levels of efficacy. For example, a study of students in India, the United Kingdom, and the United States finds that parental income is related to students' sense of efficacy (Shrivastava, 1989).

Political efficacy also varies by personality type. Mondak and Halperin (2008) observe a number of relationships between the so-called 'big-five' personality traits and efficacy. Those open to new experiences are likely to have higher levels of internal political efficacy while those more agreeable and willing to follow are less confident in their own political effectiveness but have higher levels of external efficacy. Those high on conscientiousness or who act according to plan have lower levels of both internal and external efficacy, and extroversion is positively associated with efficacy (Vecchione and Caprara, 2009). Another strand of work goes further back in the causal chain and links both self and political efficacy to a person's genetic characteristics (McGue and Bouchard, 1998; Fowler et al., 2008).

New media also has a role in developing political efficacy. Weaver's (1994) analysis of talk radio in the United States finds that those who listen to talk radio shows where listeners were able to call in and give their political opinions are less alienated, even if the direction of the news is biased (see also Banducci and Karp, 2003). In a study of college students, Lee (2006) finds that accessing traditional news sources such as newspapers increases internal efficacy. However, and unexpectedly, accessing sources of information online, particularly government sites are correlated with lower levels of external efficacy. Social network use among American and Chinese students facilitates political discussion and efficacy, particularly by those who are not otherwise civically minded or engaged (Chan and Guo, 2013).

The presence of new media may make people, both young and old alike, more aware of their political rights and increase citizens' internal efficacy as their competence with accessing political information on new media grows (Stoker, 2006). However, this more individualistic form of political activity might leave traditional political avenues out of the picture, and lower external efficacy levels as citizens come to believe that parties, campaigns, and interest groups cannot respond to the public's demands in a timely manner (Coleman et al., 2008).

The (Un)Virtuous Circle? Reciprocal Relationships and Political Efficacy

The disentanglement of the relationship between political participation and political efficacy is a complex exercise, as reciprocal effects exist between the two. In contrast to early findings suggesting levels of political efficacy develop early in adulthood and remain stable over time (cf Iyengar, 1980), elections and other political activities are found to influence efficacy levels, regardless of whether citizens are actually participating in such events (cf Clarke and Acock, 1989). The analysis of panel data from the United States and West Germany in the 1970s demonstrates that campaign activity and external political efficacy have a reciprocal relationship. Finkel's (1985, 1987) analysis of these data concludes that those who partake in high intensity political participation may grow to become more involved over time. Building on the work of Thompson (1970: 66), he notes that those active in campaigns become more confident in their own internal political efficacy which leads people to look for additional avenues of involvement in the political process (see also Finkel et al., 2000). In contrast, those protesting or embroiled in illegal political activity see their levels of political alienation grow, which can reduce their external political efficacy. This may further divide activists into two camps, those supportive of the system and those disaffected.

In his analysis of panel data, Finkel (1985, 1987) did not find that voting increased political efficacy but subsequent work establishes that external political efficacy *does* increase among the subgroup that backs winning candidates. For example, Pattie et al. (2004) find that British respondents who back the Labour Party during the late 1990s and in their 2001 re-election efforts see their political efficacy levels grow. Hence, efficacy may increase not just as a function of political participation but as a result of what Leighley (1991: 199) notes is the "perceived success of such activity" (see also Clarke and Acock, 1989; Clarke and Kornberg, 1992; Valentino et al., 2009).

Campaigns can also raise efficacy levels by paying attention to voters. Those with a history of voting and high levels of political interest are likely to engage with campaigns. Banducci and Karp (2003) find that Americans who report being contacted by a candidate or party during a campaign display higher levels of political efficacy. Some work argues that ballot initiative campaigns engage voters and may improve levels of efficacy as they are a direct way for citizens to have input into the lawmaking or constitutional design of the political system (Mendelsohn and Cutler, 2000). The number of initiatives on a ballot in an American state at a given time is also linked to improved efficacy levels among voters (Bowler and Donovan, 2002). However, Dyck and Lascher's (2009) replication of these results using more sophisticated statistical techniques cast doubt on early findings.

Reciprocal models linking efficacy to a wider variety of forms of political participation include those employed by Stenner-Day and Fischle (1992) on data from Australia and Gastil and Xenos (2010), who look at a three-wave panel study of Americans in the Pacific Northwest and uncover relationships between political efficacy and a wider range of political activities that go in both directions. The latter authors find internal, not external, efficacy is a key driver of political action other than voting, but this relationship is not reciprocated. Media use does not predict internal efficacy but the citizens' engagement with news did enhance internal efficacy. Stenner-Day and Fischle (1992) examine the reciprocal relationships between efficacy and partisan and community activism and political extremism and find considerable feedback between perceived effectiveness, perceptions of the degree to which government listens to citizens and these three forms of political and civic engagement.

Measuring Political Efficacy

Despite its importance as a precursor to political behavior in representative democracies and a long literature claiming it is something to be nurtured, social scientists have difficulty agreeing on how best to measure both internal and external efficacy. Questions measuring the concept vary, but five, whose origins date to the 1952 American National Election Study (ANES) remain prominent. They are agree-disagree questions, which read as follows: (1) "People like me have no say in what the government does"; (2) "Voting is the only way that people like me can have any say about how the government runs things"; (3) "Sometimes politics and government seem so complicated that a person like me cannot really understand what is going on."; (4) "Public officials don't care what people like me think."; and (5) "The way people vote is the main thing that decides how things are run in this country." (The fifth question did drop out of favor with those attempting to validate efficacy batteries in the 1970s (cf Balch, 1974).) In both national and cross-sectional surveys, derivatives of these questions are found, even on surveys fielded in the twenty-first century. For example, the 2002 European Social Survey, a cross-national instrument with respondents from more than 20 nations, contains derivatives of the politicians caring what people think and politics being too complicated questions (see Xena, unpublished).

Despite some consistency in the questions selected over time, variation in the questions employed to tap internal and external across surveys in the 1960s and 1970s is considerable. Balch (1974) is the first to seriously subject common indicators to tests of measurement validity and reliability, and states that questions 2 and 3 from the original ANES battery are reflections of internal efficacy and items 1 and 4 are manifestations of external efficacy. Wright (1975) and Clarke et al. (2010) examine the four items for response set or acquiescence bias, the tendency of survey respondents to agree or disagree to an item regardless of its content, and find little evidence of the problem.

Questions over which items to designate as indicators of internal and external efficacy arise after the ANES updated and enhanced the battery of questions designed to tap both types of efficacy (cf Miller et al., 1980). Specifically, Craig and Maggiotto (1982) find that it is unclear whether item 1 from the original ANES battery is an indicator of external or internal efficacy, conclude that the conceptual validity of most items are suspect, and call for the development of substitutes. In a study examining the suitability of the traditional indicators across multiple countries, Acock et al. (1985) disagree and note that standard indicators employed by the ANES are cross-nationally valid as long as sophisticated latent variable modeling is employed to derive factors of internal and external efficacy (see also Acock and Clarke, 1990). (Acock et al. (1985) designate items 2, 3, *and* 1 as indicators of internal efficacy. Indicators of external efficacy are item 4 and two questions that first appear on the 1968 ANES: "Parties are only interested in people's votes but not in their opinions," and "Generally speaking, those we elect lose touch with the people pretty quickly." The lack of clarity as to whether certain traditional indicators of efficacy are best reflective of the internal or external component continues to this day (Xena, unpublished).)

In the 1980s, the investigators of the ANES respond to the controversy over the efficacy indicators by experimenting with alternative question batteries on pilot studies in the field during the period. Testing a large item battery of potential substitutes, Craig et al. (1990) conclude with a recommendation of a new 10 question item battery, six to measure internal efficacy, and four to measure external efficacy: (1) "I feel that I could do as good of a job in public office as most other people."; (2) "I think I am as well-informed about politics and government as most people."; (3) "I don't often feel sure of myself when talking with other people about politics and government." (4) "I feel that I have a pretty good understanding of the

important political issues facing our country."; (5) "I consider myself well-qualified to participate in politics."; and (6) "Sometimes politics and government seem so complicated that a person like me can't really understand what's going on." are agree-disagree questions designed to measure internal efficacy. External efficacy is measured by ascertaining respondents' agreement or disagreement with the following statements: (7) "There are many legal ways for citizens to successfully influence what the government does."; (8) "Under our form of government, the people have the final say about how the country is run, no matter who is in office."; (9) "If public officials are not interested in hearing what the people think, there is really no way to make them listen."; and (10) "People like me don't have any say about what the government does."

Confirmatory factor analytic techniques on American data show that two distinct latent dimensions drive responses to questions 1–6 and questions 7–10. The alternative measures of internal efficacy are further validated by Morrell (2003), who recommends using items 1, 2, 4, and 5 if a four-question battery is desired, and notes that the Craig et al.'s (1990) and Niemi et al.'s (1991) measures are employed in studies by, among others, Greenberg et al. (1996), Hansen (1997), and Soss (1999). Despite the use of sophisticated measurement techniques to validate the Craig et al. (1990, 1991) measures, questions designed to tap internal efficacy that have their origins in the ANES from the 1950 and 1960s are still in widespread use, particularly in comparative studies (e.g., Anderson and Tverdova, 2001).

The measurement of external efficacy remains contentious, with items 7 and 8 from the revised efficacy battery employed by Craig et al. (1990) often considered to tap regime support and not government responsiveness to the needs of citizens. This calls into question whether these items are truly reflective of external efficacy as a concept or simply fit well with the other two indicators in measurement models. Another problem is that, depending on the study and question battery, item 10 from the revised battery is designated as reflective of both internal and external efficacy. Despite its importance as a concept, it appears that social scientists are far from agreeing on a standardized question battery to measure internal and external efficacy.

Future Research

As a longstanding topic of interest to political scientists concerned with civic life and democratic citizenship, discussions of the causes, effects, and measurement of political efficacy are unlikely to wane. The increasing capabilities of scholars to conduct surveys across space (nations) raises the possibility that proper attention can be paid to the role political institutions have in determining a citizen's views about their own political agency and how responsive are the politicians that result from the voting decisions that are translated via electoral institutions. Social scientists view majoritarian systems as power concentrating, and although they offer electorates clarity in terms of who is governing, the fact that such systems create clear winners and losers tend to leave segments of the population feeling excluded. Karp and Banducci (2008) note that representative democracies nations employing first-past-the-post electoral systems see lower levels of efficacy than those employing more proportional schemes. Further, supporters of smaller political parties are more efficacious in the former than in the latter. More such studies are likely in the future.

The improved capabilities of panel surveys, often conducted via the Internet (cf Johnston, 2008), suggests that the ability of scholars to determine how political efficacy responds to a host of 'shocks' (elections, economic downturns, wars, etc.) will improve and be an interesting avenue for future research. Better panel data can also facilitate ongoing efforts to determine how citizens in emerging and newer democracies perceive their own abilities to participate and the responsiveness of the state to their needs. This is a particularly relevant question as cross-national research finds survey respondents in developing democracies to have lower levels of external efficacy than their more established counterparts (Torcal and Montero, 2006). Finally, surveys conducted in countries that are not yet democracies ponder whether efficacy levels in these nations are strong enough to facilitate self-rule (e.g., Shi, 2000), and whether a loss in efficacy leads democracies to slip back into authoritarian or semi-authoritarian rule (Lussier, 2011; Pietsch et al., forthcoming).

Scholars do have a more nuanced view of efficacy in long-standing representative democracies, noting that it is important not to overplay the notion that falling or low levels of efficacy will lead to certain democratic decline. Although low levels of external efficacy and turnout seem to represent an important challenge for the functioning of democratic regimes and do warrant attention (see Macedo et al., 2005), they will not necessarily result in negative consequences for contemporary political systems. Along these lines, Gamson (1968) argued that certain levels of political efficacy and political cynicism are key elements for political mobilization. When internal-external efficacy gaps occur, protest may follow, potentially raising the probability that governments will pay more attention to those previously disenfranchised, which in turn can lead to civic revival. Locating potential cut points and whether this occurs in practice is an area ripe for research with emerging panel data.

The links between efficacy, regime support, and conventional political participation encourage school-based civics curriculum with designs to enhance efficacy. This is not without controversy. Modern social scientists interested in civics education advise that tasks simply designed to increase efficacy, particularly external efficacy may reduce skills acquisition. Kahne and Westheimer (2006) warn that focusing only on efficacy may mask students' exposure to the reality of power inequalities that lead to political disempowerment of marginalized groups. Further, they note that many civics-based efficacy enhancing exercises have a tendency to emphasize volunteerism with apolitical groups. In the long run, this type of activity might neither generate efficacy nor lead individuals to work on issues that fundamentally are political in nature.

Political efficacy is a concept of importance with a rich history in the social science literature that attracts attention from scholars in political science, sociology, and psychology. Many of the questions that continue to get asked are enduring – what are the antecedents and consequences of the levels of internal and external efficacy we observe among people and

how do we measure these two concepts? Others are less well established, particularly observing the role political institutions have in facilitating or inhibiting efficacy in large N, multi-level, cross-national surveys. The fact that both longstanding and emerging questions surrounding political efficacy remain vital to how scholars and pundits view the health of civic life in established and emerging democracies will act to ensure that studies of political efficacy will continue to be discussed at professional conferences, in peer-reviewed journals, and in well-received books on the topic of political participation for the foreseeable future.

Egalitarianism

Christian Hiebaum, Department of Legal Philosophy, Sociology of Law, and Legal Informatics, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Equality is a notoriously controversial value and highly contested political concept. In this article, the aim is to introduce some basic problems and different ways of thinking about equality as the main ingredient of any egalitarian conception of social justice. Section The Beginnings of Modern Egalitarian Social Thought gives a rough sketch of the early history of modern egalitarian theorizing; Section Post-Rawlsian Egalitarianism presents two paradigms of recent egalitarian reasoning about the meaning of equality; Section The Site of Egalitarian Demands addresses the debate about the proper site of equality; and Section The Scope of Egalitarian Demands deals with different egalitarian approaches to the question of the scope of equality.

Introduction

'Egalitarianism,' as it is understood here, applies to left-liberal, social-democratic, socialist, and anarchist political and social theories that focus on, and proceed from the assumption of, equality as the core of social justice. Though it is perfectly reasonable to say that one may be an egalitarian in this but not in that social context (for example in the realm of health care or family or sexual relations but not with regard to the distribution of income and wealth), in this article, egalitarianism is treated as a broader (often implicit) approach to questions of how society should and could be organized. As different social systems, institutions, and practices depend on each other, however, such a broader approach also pertains to the analysis of social microcontexts.

Equality, above basic equality of humans as moral subjects, is a notoriously controversial value and highly contested political concept. Who is or should be equal to whom? In what sense, or in what respect, should people be equal? How does equality relate to other values such as freedom (or liberty), solidarity, peace, and efficiency? Do norms of equality as principles of social justice only apply to social institutions or also to individual conduct? How much inequality does actually exist within different nation-states and at the global level, and how is it to be explained? Is equality a viable social state, and is it achievable? While the former issues are primarily dealt with by ethicists and political philosophers, the answer to the questions of the degree of existing inequalities and of viability and achievability more obviously depends on knowledge only social and behavioral sciences can provide.

Thus egalitarianism also inspires empirical research and analysis, particularly in the fields of economics, sociology, and psychology. As a matter of fact, egalitarian, or 'critical' or 'progressive' or 'emancipatory,' theorizing and research shows a strong tendency to blur the boundaries between empirical and explanatory disciplines as well as between social science and normative reflection without, however, fully abandoning the division of academic labor as it is suggested by the distinction between the issues of desirability, viability, and achievability (see Wright, 2010: 20–25).

In this article, the main focus lies not on equality itself. The aim is rather to introduce some basic problems and different ways of thinking about equality as the main ingredient of any egalitarian conception of social justice, as a ground of social criticism, and as a goal of, as well as a constraint on, political practice. Section The Beginnings of Modern Egalitarian Social Thought gives a rough sketch of the early history of modern egalitarian theorizing; Section Post-Rawlsian Egalitarianism presents two paradigms of recent egalitarian reasoning about the meaning of equality; Section The Site of Egalitarian Demands addresses the debate about the proper site of equality and social justice; and Section The Scope of Egalitarian Demands deals with different egalitarian approaches to the question of the scope of equality and social justice.

The Beginnings of Modern Egalitarian Social Thought

Egalitarian thought has a long history (see Phelps Brown, 1991). The history of egalitarianism as a social attitude and practice is even longer (see Boehm, 2000). In the following, however, we will only take a look at the debates and theoretical frameworks right before the development of the most recent egalitarian theories of justice.

The beginning of political modernity is marked by freedom and equality together with solidarity becoming political values (that is, values to be realized in this world and not just in afterlife). In the early days it used to be mainly natural rights doctrines that grounded criticism of social hierarchies and privileges and policies of liberalization and democratization. Social thinkers of the Enlightenment (among others Baruch de Spinoza (1632–77), John Locke (1631–1704), Pierre Bayle (1647–1706), Baron de Montesquieu (1689–1755), Voltaire (1694–1778), and Jean-Jacques Rousseau (1712–87)) provided for the rationalization of discontent that drove movements such as the Levellers and later on the revolutionaries in France and other countries. Roughly at the same, though not exactly for the first time, feminists *avant la lettre* such as de Olympe de Gouge (1748–93) and Mary Wollstonecraft (1759–97) criticized the marginalization and exclusion of women in social life as well as in human rights thought.

The nineteenth century brought about another broadening of the focus of social criticism. It became clear that equality

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03127-5

requires more than equal (formal) liberty rights, that it is incompatible with huge economic, political, and other social differences – particularly, with large parts of the population living in misery and poverty, exploited and without access to political decision-making. The theoretical frameworks most useful to egalitarian movements were utilitarianism and socialism. Both utilitarian ethics and economics and socialist theory suggested more or less radical reforms toward more equal socioeconomic conditions or, in the case of Marxism, even predicted a revolution supposed to implement equality or 'real freedom' (as opposed to mere formal liberty).

Utilitarianism pervaded economics and became a major precursor of modern welfare economics. It may be characterized as proto-egalitarian. While utilitarians did not consider equality as an end in itself, they proceeded from the assumption that happiness or welfare in society should be maximized without distinguishing according to preexisting status and wealth. Furthermore, they had a powerful argument for more equal distribution of income and wealth: the 'law of diminishing marginal utility' of money which supports redistribution, for example, by way of progressive taxation, from the rich to the poor as a means to enlarge, directly as well as indirectly (through various side effects), the aggregate welfare of the society.

Whereas utilitarianism as a social, political, and economic theory thought of equality as a means to increase total utility, socialism treated equality as an end in itself, identical with real freedom. However, in contrast to other forms of socialist thought (referred to as 'utopian'), the most systematic and thoroughly theorized version of socialism did not conceive itself as a normative doctrine, let alone an ethical conception. Still, there are good reasons to ascribe an implicit egalitarian theory of justice to Karl Marx (1818–83) and his followers.

To be sure, there have always been serious opponents to egalitarian thought: conservative, libertarian, and social Darwinist political, social, and economic theories. At the beginning of the twentieth century, another intellectual threat to theoretical frameworks that were, at least, friendly to egalitarians appeared: skepticism about the possibility of interpersonal comparisons of well-being together with the idea that scientific analysis ought to be value-neutral. Later on, however, Keynesian macroeconomics provided for a new paradigm attractive to moderate egalitarians by giving them new arguments to keep economic inequalities within limits. More radical egalitarians without sympathy for a Sowjet-style economy built their hopes on almost simultaneously emerging theories of market socialism. Yet Keynesianism proved to be politically more effective in the Western world, that is, a framework for policy debates and bargaining between social partners antiegalitarians had a much harder time to reject.

For quite a long period of time, however, systematic reasoning about social justice, about its meaning and principles, was not considered a worthwhile academic exercise. This period came to an end when John Rawls's *Theory of Justice* (Rawls, 1971) appeared. The question of what it means to live in a society of free and equals became a theoretical issue again – dealt with not only by philosophers but also by economists and other social scientists. Though Rawls's liberal conception of social justice was quite commonly considered egalitarian, doubts among sympathetic critics arose as to whether it was properly or sufficiently egalitarian. Hence the question what 'equality' and 'egalitarian' actually mean became an important issue in political theory (while at the same time Hayekian neoliberalism gained momentum in extra-academic politics). Even pronounced socialists who had lost faith in the traditional modes of Marxist analysis participated in the debate reconstructing (parts of) Marxist social theory by making use of the methods of neoclassical economics, game theory, and analytic philosophy (Roemer, 1986). Egalitarianism ceased to be mainly instrumental egalitarianism or a prediction. It became a paradigm of its own in normative theory and its associated fields of empirical research (Bowles and Gintis, 1998; Holtug and Lippert-Rasmussen, 2007). In contrast to the other major debate following *A Theory of Justice*, namely the debate between liberals and communitarians, the controversy about egalitarianism continues to flourish.

Post-Rawlsian Egalitarianism

Today, not only is there much disagreement between egalitarians and non- or antiegalitarians, we do not have much agreement between professed egalitarians about the proper form of egalitarianism either. But genuine egalitarians seem to have one thing in common: they believe in equality not just for instrumental reasons. They consider equality also intrinsically valuable or morally required regardless of consequences, though social scientists with an egalitarian political outlook naturally tend to focus on the consequences of real or hypothetical institutions of equality (asking which egalitarian institutions work and which do not, and why some such institutions work or fail or do not come into existence in the first place).

On the other hand, bad consequences of what appears to be an egalitarian social arrangement may raise doubts among egalitarians about their conception of equality. Social facts as well as facts about the genetic endowment and psychological capabilities or propensities of human beings may influence beliefs of what equality, properly understood, consists in. They may be taken as specifications of what Rawls, following David Hume, has termed "the circumstances of justice." However, not all egalitarians accept the idea that empirical research can contribute to the determination of the content of fundamental moral values – just like positivistically minded social researchers typically want to keep their work free from 'unscientific' and purportedly necessarily subjective reflection about moral values. At least it remains undisputed that the application of norms of social justice and the realization of egalitarian social arrangements require lots of empirical knowledge. For example, whatever we may think of the Rawlsian difference principle, whether it is fulfilled or whether the capitalist welfare state is capable of maximizing the minimum, certainly is, to a considerable degree, an empirical question dealt with by social scientists as well as philosophers.

Egalitarians agree that many political and economic inequalities of the modern capitalist society cannot be plausibly justified by any reference to social equality. Beyond that, the views of egalitarians diverge. We can roughly distinguish two sorts of egalitarians: those who cling to a narrow,

distributive paradigm of equality and those who are committed to a more comprehensive, relational understanding. The former approach seems to prevail in egalitarian analytic political philosophy and welfare economics, while the latter is more popular among egalitarians that prefer to blend philosophy, sociology, and anthropology.

Narrow Egalitarianism

Narrow egalitarianism, which, for some time from the 1980s onward, almost epitomized egalitarianism, focuses not on relations between people but on the distribution of goods. Accordingly, 'equality' means equal distribution of goods. Given such a definition, the question arises as to which goods are to be distributed equally. And given that some differences and inequalities are unavoidable or obviously justified, we have to look for an abstract cardinal good: (access to) welfare, opportunities, (access to) advantages, capabilities, resources, or something else. Narrow egalitarians have spent many years searching for such a cardinal good and discussing various proposals (Arneson, 2011; Hausman and McPherson, 2002: 135–159). Furthermore, they maintain that the cardinal good should be distributed in a luck-neutralizing way. This line of reasoning constitutes what is now termed 'luck egalitarianism.' It is inspired by Rawls's suggestion "to regard the distribution of natural talents as a common asset" and to not let the morally arbitrary natural lottery determine the distribution of social goods (Rawls, 1971: 101). According to luck egalitarianism, "an unequal distribution whose inequality cannot be vindicated by some choice or fault or desert on the part of (some of) the relevant affected agents is unfair, and therefore, *pro tanto*, unjust, and nothing can remove that particular injustice" (Cohen, 2008: 7). In other words, the distribution should be ambition-sensitive and endowment-insensitive (Dworkin, 2000: chapter 1 and 2).

Whatever the cardinal good that is supposed to be distributed in such a way, it seems clear that this account of equality relies heavily on a distinction between choice and (unchosen) natural as well as social circumstances. By that, luck egalitarianism retains some connection to widespread intuitions about why, for example, racist and sexist discrimination is wrong. For, roughly speaking, being discriminated is commonly conceived of as being disadvantaged (by authorities, norms, and institutions) just because of an unchosen property one cannot (reasonably be expected to) dispose of. Luck egalitarianism also appears compatible with the belief that humans are responsible agents, and that individual choices and efforts should make a difference in the distribution of goods, especially of material wealth. At least in theoretical discourse, egalitarianism thus takes a powerful idea away from its opponents and incorporates it into a critique of precisely those inequalities that used to be defended through reference to individual responsibility. It seems to take responsibility and individual desert more seriously than most self-declared proponents of meritocracy on the antiegalitarian side.

However, according to other egalitarians (and, needless to say, of non- and antiegalitarians), the fact that luck egalitarians lay so much stress on the distinction between choice and circumstance amounts to a serious shortcoming of their conception of social justice. For this distinction not only opens up the field for empirical research, it may also lead us deeper into metaphysical terrain than social analysts as well as political thinkers and actors are willing to go. Furthermore, by itself luck egalitarianism looks sociologically sterile. It seems to be mainly concerned with the question of desirability (less with feasibility, and still less so with achievability) and tends to separate distributive equality all too neatly from other politically relevant values. For luck egalitarians, says G.A. Cohen, "are interested in the very nature of distributive justice, not in the different question as to what principles, to be influenced by distributive justice *but also by other things*, a society should adopt as its basic ones" (Cohen, 2008: 301).

Just think of persons who remain paralyzed after being injured due to imprudence or as a consequence of a risky undertaking such as mountain climbing. Most people believe that they have a right to special therapy and care. And many, at least in Europe, would hesitate to bill them for the full costs of such provisions and to consider social disadvantages resulting from so caused disability not in need of further justification just due to their being 'self-inflicted.' Now, luck egalitarians might reply that they are not that stonehearted either, that there are other values beside equality to be taken into account. Often equality has to be traded off against solidarity, the right to health care, or subsistence, etc. Equality is just one important value among others. Some luck egalitarians even hold that to attribute intrinsic value to equality implies the belief that a society consisting only of blind people is better in at least one respect than a society in which not all are blind. It's just other values which, in the latter society, prevent egalitarians from putting out the eyes of the sighted (Temkin, 1993: 257).

Comprehensive Egalitarianism

In contrast to luck egalitarianism, comprehensive egalitarianism is primarily concerned with equality as an ideal referring to relations between people free from oppression and dominance (Anderson, 1999, 2012; Scheffler, 2003; Walzer, 1983; Young, 1990). Though to some degree a reaction to luck egalitarianism and what is perceived as its shortcomings, comprehensive egalitarianism seems, in spirit and conceptually, closer to historical and current political movements against, and empirical analyses of, social inequality. Accordingly, egalitarians are supposed to take aim at "different types of social hierarchy, including slavery, serfdom, debt patronage, feudalism … oligarchy, caste and class inequality, racism, patriarchy, colonialism, and stigmatization based on sexuality, disability, and bodily appearance" (Anderson, 2012: 40). It is not denied that social relations are shaped by distributions of goods and that, among the dimensions of social justice, distributive justice has a special relevance. Yet according to comprehensive egalitarians, it is a variety of social goods the distribution of which brings about relations of equality or inequality, and some goods, such as basic legal rights, have to be distributed quite equally regardless of choice and luck.

Thus comprehensive egalitarians, while granting that in some contexts justice has a lot to do with neutralizing luck, do not aim at determining a cardinal good whose equal (or ambition-sensitive/endowment-insensitive) distribution defines equality. The questions guiding their research and reflection are: What is the role of social equality in evaluating

institutions and actions? Which set of principles of distribution and of the treatment of human beings are compatible with, or conducive to, social equality under which circumstances, or rather in which contexts? When, for example, does the argument of differential effort or productivity outweigh the argument of need? What is the relevance of legitimate expectations? How are egalitarian societies organized, or how could they be organized? Which principles are egalitarian as such, that is, just in virtue of their content, is not an issue comprehensive egalitarians are much interested in.

This version of egalitarianism is comprehensive in two respects: first, it is not just concerned with economic distributive justice but also with transactional justice, political justice, and corrective justice; and second, it refers more to all-embracing social orders and less to distributional microcontexts. Thus, it implies, or demands for, some kind of second-order theory, even of distributive justice. Assuming that there will always be disagreement about the justice of particular distributions, comprehensive egalitarians deny that social equality amounts to distributive justice all the way down. They maintain that social equality should not be identified with perfect (and notoriously contested) economic distributive justice – that, up to a certain degree, it allows for deviation from distributive ideals provided that there remains a political space for challenging ideals and what is taken as deviations.

So, comprehensive egalitarians conceive of social equality as a feature of persons living in various overlapping social relationships that are partly characterized by distributions of goods, not as a feature of distributional patterns themselves. Whatever social equality amounts to in detail, comprehensive egalitarians define it as a distributional state together with certain (though perhaps not fully compatible) public justifications. For equals have to have good reasons to consider themselves equal. An accidental distribution which is compatible with equality at a particular point of time is not enough. Neither is the mere belief that we are all equals. Accordingly, any strict distinction between egalitarian distribution and its justification is a priori impossible. Distribution relates to its justification roughly like equality of outcome to the treatment of people as equals, or like equality as a political goal to equality as a side constraint of political action.

Not only do luck egalitarians disagree with each other, there is also lots of disagreement among comprehensive egalitarians. A good deal of disagreement has its sources not just in different views of what is just or unjust, but in different perceptions of how society is best described and in competing accounts of existing hierarchies. Take the debate about multiculturalism. It is now commonplace that 'progressive' or leftist social science all too long ignored the fact that there are noneconomic dimensions of social life that cannot be treated as mere epiphenomena of the division of classes. One such dimension is supposed to be culture. Though most political thinkers and social scientists agree that, in modern society, no social sphere is in principle more basic than all the others, there is still some debate about whether culture constitutes such a sphere, whether 'culture' is an analytically useful concept, what 'cultural equality' means and how cultural identity relates to other aspects of individual identity, and whether collective rights to 'cultural identity' should rank high on the egalitarian political agenda (see Barry, 2001; Kymlicka, 1995).

Debates such as this one (with a notorious propensity to go on forever) might be viewed as a serious weakness of comprehensive egalitarianism. For they suggest that it lacks conceptual, normative, and methodological coherence, at least compared to luck egalitarianism. Comprehensively egalitarian theories and analyses seem to display little more than family resemblances. To luck egalitarians, comprehensive egalitarianism looks like a set of theories that are not properly characterized as egalitarian at all, but rather as prioritarian (such as the theory of Rawls, 1971), or even merely sufficientarian (such as the conception of 'democratic equality' of Anderson, 1999). It appears prioritarian insofar as it proposes principles that demand for special consideration of the fate of the least advantaged. And it appears sufficientarian to the degree that it only requires us to make sure that no member of society falls below a certain threshold of well-being (whatever that threshold may be). That comprehensive egalitarianism is less vulnerable to antiegalitarian challenges (as it incorporates a plurality of values into the framework of equality) thus does not seem to be much of an asset. On the other hand, the looseness of comprehensive egalitarianism might simply be the price of not restricting political thinking and social research to conceptual analysis, questions of desirability, and abstract modeling. That is, it might just be a reflex of the complexity of social reality itself with its multiple layers and intersections of differences and inequalities.

The Site of Egalitarian Demands

Another question is whether egalitarianism should be concerned exclusively with institutions or whether it should also cover personal behavior, or rather: whether norms that apply to institutions and are supposed to guarantee equality should equally guide us in our private lives. This, of course, is an issue every theory of social justice (not just egalitarian ones) has to deal with.

Historically, liberalism as well as socialism (particularly orthodox Marxism) used to show a strong bias toward institutions and structures and to be highly skeptical about moralizing. Such a bias even seems to be typical of secular social thought. Religious social ethics has always been more open to the idea of individual duties of social justice and solidarity transcending the duty to create and preserve just institutions.

So what, if anything, does equality as the central value of social justice require from us in terms of personal behavior? Those who believe that equality applies equally to institutions and personal conduct use to be referred to as 'monists,' those who insist on a more or less strict separation of the sites of social justice are called 'dualists.'

Monism

Monists claim that norms of equality should also motivate us to do more than egalitarian institutions demand from us (see Cohen, 2000). The wealthy, for example, should also give part of their after-tax income to the poor, directly or indirectly via

charity organizations or by way of unsalaried community work, in order to further reduce economic inequality. Or to put it differently: a widespread individual ethos is part of the basic institutions of society. In this sense, the personal is considered political.

That is, monists reject the idea that if we get the economic and legal institutions right individuals may always act selfishly, provided they comply with the institutionalized rules. On this view, the attitude of selfish individuals who still affirm, and comply with, egalitarian institutions, though psychologically possible, is less than fully coherent.

Dualism

Dualists insist that it does not make good sense to require individuals to comply with principles such as Rawls's difference principle for pragmatic, epistemic, and moral reasons (Pogge, 2000). Sharing more of one's wealth than egalitarian institutions require with the poorer members of society may be virtuous but it is not a clear duty that follows from a reasonable egalitarian conception of social justice (be it a luck-egalitarian or a comprehensive-egalitarian conception).

Dualists concede that the proper design of the institutions may, to some degree, depend on the ethos spread in a population. For after all, how progressive a tax system should be varies with what financial incentives are necessary for the talented to make efforts which also benefit the others. However, due to the fact that not only the poor but also the rich and productive face collective action and free rider problems, attempts at blackmailing the rest need not to be taken very seriously. That is, claims of the wealthy to the contrary notwithstanding, we could, at least through international cooperation, impose significantly higher taxes on high income and wealth and thus create much more economic equality without necessarily reducing the size of the cake that is to be distributed.

The Scope of Egalitarian Demands

As to the issue of the proper scope of egalitarian thinking as thinking about social justice, we can distinguish between particularistic and cosmopolitan approaches. This distinction cuts across the distinction between luck egalitarianism and comprehensive egalitarianism. (Though, at first glance, luck egalitarians might be expected to naturally prefer the cosmopolitan account of justice since they use to skip over the question about the kinds of social relationships that have to obtain for equality to become an issue at all. Thus they appear to be committed to extend the scope of equality beyond relations between compatriots or members of a community of another type.)

Particularists argue that egalitarian conceptions of social justice or norms of equality only apply to already existing political communities, while cosmopolitans believe that social justice with equality at its center has a significant transnational or global dimension. Obviously, particularism corresponds to a long tradition in social thought of roughly (and often implicitly) equating society with something organized as state, sometimes referred to as the 'container theory of society' or "methodological nationalism" (Beck and Sznaider, 2006). In the field of empirical research and theorizing, this tradition is reflected by the (once quite strict) disciplinary division of political science and international relations theory. In contrast, cosmopolitanism seems to be more in line with antistatist, internationalist, or globalist accounts of society (which, to be sure, also have a history that goes back to the beginnings of the social sciences).

Particularistic Egalitarianism

According to particularistic egalitarianism, equality is a domestic or intracommunal issue or something primarily concerning the treatment of citizens by their government (Blake, 2001; Miller, 2007). There may be moral norms whose scope transcend communal boundaries and state borders, but either (1) they are not norms of social justice, as opposed to, for example, norms that impose humanitarian duties, or (2) if they are norms of justice, they do not derive from the value or some norm of equality, as opposed to, for example, the principle of sufficiency.

Particularistic egalitarians, just like many non- or antiegalitarians, do think that the affluent have moral duties toward the global poor, or, at least, a collective responsibility. However, they deny that the ideal of equality makes good sense at the global level. In addition to considerations of feasibility and achievability and (occasionally) relativistic assumptions about the origins, existence, and objectivity of moral values, particularistic egalitarians put forward, at least, three arguments: (1) the argument from cooperation; (2) the argument from solidarity; and (3) the argument from coercion.

1. Egalitarian demands presuppose a certain type of cooperation, that is, not just 'ordinary' social cooperation but also a cooperative determination of the terms of social cooperation through democratic decision-making. At the global level, we may have interaction that can be described as cooperation, yet we lack institutions of political cooperation and democratic decision-making. Without such basic political institutions, it does not make sense to raise claims to equality against each other.
2. The argument from cooperation is often supplemented by the claim that political cooperation depends on a sense of solidarity and belonging, on loyalty that cannot be directed at the whole of mankind but is naturally much more exclusive. Social equality transcends mere equal moral standing and thus requires a closer bond between individuals than mutual respect. This argument may be backed by anthropological evidence about the limits of our inborn capability to identify with socially or geographically distant others.
3. Egalitarian concerns are triggered by the use of political force directly constraining individual autonomy. For such coercion creates a demand for justification that also requires the application of 'relative' principles of justice. Since there is no such direct political coercion of individuals at the global level, the issue of equality remains restricted to the domestic level.

Cosmopolitan Egalitarianism

According to cosmopolitan egalitarianism, equality is not only relevant to relations between members of a particular political

community, or to the distribution of goods and burdens among them, but also to the design of global political and economic institutions. It may even be a ground of individual duties toward people in other parts of the world. To the degree that society is globalized, social justice should have a global dimension that transcends mere international justice (Beitz, 1999; Brock, 2009; Caney, 2005).

With regard to social theory and empirical analysis, cosmopolitans reject what they refer to as "explanatory nationalism" (Pogge, 2002: 139–144), that is, the tendency to deny or ignore the impact of global (particularly economic) institutions on the distribution of resources and on democracy within the state. With regard to the particularistic arguments mentioned above, most cosmopolitans concede that such arguments give us good reasons not to believe that social equality at the global level means exactly the same as domestic social equality or that we should hope for particular political communities or states to give way to a world state. Still, cosmopolitans deny that these arguments convincingly define the scope of social equality:

1. While it is true that social equality as a matter of fact depends on political cooperation, it may also create a demand for new or modified political institutions. What is more, we already have firmly institutionalized global political decision-making, for example, within the World Trade Organization. But it is highly and unfairly biased in favor of the most powerful states and economic actors. Moreover, some global institutions, such as the borrowing and resource privilege (Pogge, 2002: 112–116), create strong incentives for governments to not even try to represent the interests of their citizens or, prior to that, for particular groups within a country to seize power by undemocratic or violent means.
2. Solidarity between compatriots is solidarity between strangers, consisting, to a large degree, not in mutual sympathy but in accepting, and complying with, institutions and the underlying quite abstract values. Patriotic solidarity is certainly valuable, but it is also a highly 'artificial' thing (compared to egalitarianism in hunter-gatherer societies) partly generated precisely by the political, educational, and welfare state institutions it is supposed to support.
3. Apart from the fact that some global or transnational institutions may constrain individual autonomy quite directly, we have also lots of indirect political coercion within the state whose justification includes considerations of equality and requires the application of relative principles of justice. Take as an example tax law which needs to be justified not only to those who are taxed but also to those who may be indirectly affected (through higher prices, less capital investment, etc.).

Conclusion

What seems clear is that reasonable egalitarianism applying to modern society, whether national or transnational, differs in many ways from egalitarianism as an attitude and practice in much less complex communities or in social microcontexts. It certainly requires a significant widening of moral concern and the ability to get motivated by more abstract conceptions of justice. One might thus believe that, today, egalitarianism deserving its name demands too much from people. As a matter of fact, early 'gene-centered' sociobiology, sometimes contrary to the intentions of its exponents, showed a tendency to nourish skepticism about egalitarianism beyond kin groups. However, more recent research in evolutionary psychology, experimental economics, and game theory, though far from supporting a view of human beings as fully constituted by culture and social institutions and therefore radically malleable, let modern egalitarian hopes appear much less incompatible with human nature (Bowles and Gintis, 2011).

Eisenberg's Theory of Prosocial Reasoning

Bilge Yagmurlu and Hilal Sen, Koc University, Istanbul, Turkey

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, we present information about Eisenberg's prosocial moral reasoning. Prosocial moral reasoning focuses on the moral justifications behind prosocial actions intended to benefit another person. There are five levels of prosocial moral reasoning, progressing from self-centered concerns to other-oriented and value-related concerns. This change in prosocial moral reasoning is partly related with improving empathic, sympathetic, and perspective-taking skills. Finally, there is a positive association between prosocial moral reasoning and prosocial behavior, but motivational and situational factors are also important in this relationship.

In everyday life, people encounter different dilemmas in which they decide whether to help a person or not; sometimes they may even have to decide whether to violate a law in an emergency situation. The way that people resolve moral conflicts is considered to be related to their level of moral reasoning. Eisenberg defines prosocial moral reasoning as "reasoning about conflicts in which the individual must choose between satisfying his or her own wants or needs and those of others in contexts in which laws, punishments, authorities, formal obligations, and other external criteria are irrelevant or deemphasized" (Eisenberg-Berg, 1979: p. 128). In this sense, *prosocial moral reasoning* focuses on moral judgments that pertain to positive social behaviors intended to benefit another person. The dilemmas that tap such situations are widely experienced in real life.

Eisenberg (1986) proposes a scheme that portrays age-related changes in prosocial moral reasoning, from childhood to adulthood. This scheme is presented in **Table 1**.

According to Eisenberg (1986), there is a progress from self-centered concerns to other-oriented and value-related concerns in prosocial moral reasoning. At the lowest level of prosocial justifications, self-focused (hedonistic) concerns are central; engaging in prosocial behaviors is determined by selfishness (i.e., gaining reward or reciprocity). At the second level, the needs of others are emphasized but not in a sophisticated way. That is, individuals may refer to other's needs without any reference to empathic concerns for the welfare of the needy one. At the third level, engaging in prosocial behavior is decided by the consideration of the approval of others. There is a motivation for having a good impression in others' eyes. At the fourth and fifth levels, more mature forms of reasoning are apparent. At the fourth level, the emphasis is on empathic concerns for other people and taking their perspective. Then, there is a progress to internalized values, norms, and goals to improve the conditions of individuals at the fifth level.

Although the rudimentary needs-oriented orientation in moral reasoning is a relatively low level of prosocial moral reasoning, Eisenberg (1986) argues that needs-oriented moral reasoning is different from self-oriented or pragmatic categories of reasoning, as highlighted by the negative correlation between needs-oriented and self-oriented moral reasoning. She also claims that needs-oriented reasoning overlaps with empathic reasoning categories. Moreover, in their pencil-and-paper measure of moral reasoning used with adolescents and adults, Eisenberg and colleagues (e.g., Carlo et al., 1992; Eisenberg et al., 2002) argue that approval-oriented reasoning is at a lower level than needs-oriented reasoning.

Issues in Kohlberg's Assumptions: Eisenberg's Approach to Moral Reasoning

Eisenberg (1986) questioned Kohlberg's assumptions about moral judgment. In his model of moral reasoning, Kohlberg (1969) proposed that stages of moral reasoning are hierarchically integrated, structurally whole, invariant, and qualitatively different. The assumption of hierarchical integration suggests that when an individual is at higher stages of moral reasoning (stage 4 or 5), he or she reorganizes lower levels of reasoning into his or her current level, so the individual cannot make reasoning at lower levels (stage 1, 2, or 3). Eisenberg (1986) argued that a given individual's moral reasoning can occur at a variety of levels. Within any level of cognitive development, individuals can reason at different levels. She found that adolescents produced both higher and lower types of moral reasoning at the same time for different dilemmas (Eisenberg-Berg, 1979). Therefore, Eisenberg (1986) argued, hierarchical integration is not correct for the nature of moral judgment. Kohlberg's structural wholeness assumption considers each stage as a reflection of an underlying thought organization; hence, responses at a stage are not random, and they reflect an underlying systematic thinking or reasoning. This is in part due to the scoring system of Kohlberg. In his coding scheme, the variation in moral responses is minimized by eliminating infrequent levels of moral reasoning, emphasizing only consistently produced levels of moral reasoning. This procedure loses nuances in moral judgments and results in an artificial homogeneity in moral responses, indicating that individuals generate similar responses as if they are at one stage. According to Eisenberg (1986), however, a structural wholeness assumption is not accurate because people produce reasoning at a variety of levels.

Eisenberg (1986) also argued that invariance in the sequence of stages (i.e., the sequence of stages does not change) does not depict the nature of moral development

Table 1 Eisenberg's levels of prosocial moral reasoning

Level	*Explanation*	*Age*
Level 1. Hedonistic, self-focused orientation	The individual is concerned with self-oriented consequences rather than moral considerations. Reasons for assisting or not assisting another include consideration of direct gain to the self, further reciprocity, and concern for others because one needs and/or likes the other (due to affectional ties).	Predominant mode primarily for preschoolers and younger elementary-school children
Level 2. Needs-oriented orientation	The individual expresses concern for the physical, material, and psychological needs of others even though the other's needs conflict with his or her own needs. This concern is expressed in the simplest terms, without clear evidence of self-reflective role taking, verbal expressions of sympathy, or reference to internalized affect such as guilt.	Predominant mode for many preschoolers and many elementary-school children
Level 3. Approval and interpersonal orientation and/or stereotyped orientation	Stereotyped images of good and bad persons and behaviors and/or considerations of others' approval and acceptance are used in justifying prosocial or nonhelping behaviors.	Predominant mode for some elementary and many high school students
Level 4a. Self-reflective empathic orientation	The individual's judgments include evidence of self-reflective, sympathetic responding or role taking; concern with the other's humanness; and/or guilt or positive emotion related to the consequences of one's actions.	Predominant mode for a few older elementary school children and a moderate number of high school students
Level 4b. Transitional level	The individual's justifications for helping or not helping involve internalized values, norms, duties, or responsibilities; show concern for the condition of the larger society; or refer to the necessity of protecting the rights and dignity of other people. These ideas, however, are not clearly or strongly stated.	Predominant mode for a minority of people high school age or older
Level 5. Strongly internalized stage	Justifications for helping or not helping are based on internalized values, norms, and responsibilities; the desire to maintain individual and societal contractual obligations or improve the condition of society; and the belief in the dignity, right, and equality of all individuals. Positive or negative emotion related to the maintenance of self-report for living up to one's own values and accepted norms also characterizes this stage.	Predominant mode for only a small minority of high school students and no elementary school children

well. Moral reasoning does not follow a strict path, and individuals can show variation in their moral reasoning development. Eisenberg also asserted that moral stages might not be qualitatively different from each other, implying that some stages could be parts of an underlying general theme. As Carlo et al. (2008) demonstrated, adolescents' stage 4 and 5 prosocial moral reasoning responses loaded on the same factor, suggesting that they are parts of an overarching value such as *internalized concerns for other's welfare*. In summary, according to Eisenberg, the stages of prosocial moral reasoning are not invariant, structured whole, qualitatively different, and hierarchically integrated, although they do tend to emerge in a given order due to constraints on children's socio-cognitive abilities. In addition, she argues that individual differences in prosocial moral reasoning are affected by individuals' socio-cognitive skills such as empathy and perspective taking, socialization practices, and situational factors (see subsequent sections of this article for the details).

Age and Gender Differences in Prosocial Moral Reasoning

A series of cross-sectional and longitudinal studies were conducted in order to delineate age-related changes in prosocial moral judgment. Eisenberg and colleagues reported that young children are prone to use lower levels of reasoning; and older children and adolescents tend to use higher levels of moral reasoning (e.g., Eisenberg, 1986; Eisenberg et al., 1995). In other words, the justifications of young individuals often focus on self-related issues and personal gains or future reciprocity. Older individuals, in contrast, rely on more advanced levels of reasoning and emphasize internalized values, sympathetic concern, and perspective taking with regard to engaging in prosocial behaviors. Many other findings have also supported similar age-related differences in other cultures like Turkey (Kumru et al., 2012) and Brazil (Carlo et al., 1996).

Specifically, the findings of Eisenberg's longitudinal studies (Eisenberg et al., 1987, 1991, 1995, 1999, 2002, 2005) indicate that the most dominant response in prosocial moral reasoning interviews is hedonistic (stage 1, including self-oriented responses) in the preschool period, although needs-oriented responding is fairly frequent. During the preschool and elementary school years, the frequency of hedonistic responses decreases, while at the same time need-oriented concerns increase. Approval-oriented responses emerge in elementary school and are most frequent in the secondary school years. In the high school years, empathic concerns, perspective taking, and internalized values become more common, although adolescents more frequently verbalize needs-oriented, stereotypic, and approval-oriented reasoning. Needs-oriented reasoning declined in adolescence, whereas there is evidence of fluctuations in stereotypic and approval-oriented reasoning across adolescence and early adulthood. Overall, those results demonstrated that there is an increase in the sophistication in the level of moral reasoning from childhood to adulthood.

Findings with regard to gender differences are more mixed. A meta-analysis on gender differences in moral orientations indicated that females performed higher on caring and prosocial moral reasoning compared to males, but the difference was small (Jaffee and Hyde, 2000). However, studies also revealed that the marked difference between females and males in higher forms of moral reasoning that emerges in early adolescence (Eisenberg et al., 1991, 1995) begins to diminish by late adolescence (Carlo et al., 1992), probably because maturation in perspective taking and empathy, which are significant correlates of higher forms of moral reasoning, minimizes the gap between females and males. Nonetheless, gender differences favoring women were still evident in the 20s and early 30s, although the higher level of hedonistic reasoning used by males dropped off across the 20s (Eisenberg et al., 2005, 2013).

The reported difference in moral justifications between females and males might be due to gender-specific socialization practices (Eisenberg, 1986; Gilligan, 1982). From very early on, females are encouraged to care for the other, both the younger and older, and are expected to be empathetic with others' concerns. All of these practices endorsed by different parties in society (e.g., family, friends, neighbors, or school) foster the skills of taking others' perspective and understanding their needs. This may underlie females' use of more needs-oriented and empathy-oriented reasoning as a motive for moral justifications.

Socio-Cognitive Skills in Prosocial Moral Reasoning

Eisenberg (1986) emphasized the importance of empathy and perspective-taking skills in moral judgment. Previous theoretical arguments (Kohlberg, 1969; Underwood and Moore, 1982) basically focused on the advancement of cognitive skills as a precursor to sophistication in moral reasoning. In this respect, maturation in taking the perspective of another person cognitively is regarded as central to moral understanding. Nevertheless, along with cognitive aspects, Eisenberg (2005) argued for the role of affective aspects in moral judgment, like empathy and sympathy. In general, improvements in empathy and perspective taking are linked to advanced levels of moral reasoning. As individuals master these skills, they produce more needs-oriented reasoning and internalized values, and lower levels of self-directed or hedonistic reasoning (Eisenberg et al., 1999, 2002).

Affective Side: Empathy

Empathy is considered to activate internalized moral values such as concern for other people's benefit and welfare (Hoffman, 2000). Eisenberg (2005) also highlighted the role of empathy in prosocial moral reasoning and responding. She defined empathy "as an affective response that stems from the apprehension or comprehension of another's emotional state or condition and is similar to what the other person is feeling or would be expected to feel in the given situation" (Eisenberg, 2005: p. 75). In this conceptualization, empathy often evokes two different emotional reactions: *sympathy* and *personal distress*. These two emotional reactions include a certain degree of cognitive aspect such as perspective taking and might be experienced separately or

simultaneously. *Sympathy* refers to "an emotional response stemming from the apprehension of another's emotional state or condition that is not the same as the other's state or condition but consists of feelings of sorrow or concern for the other" (Eisenberg, 2005: p. 75). Thus, feeling concerned about a person, but not experiencing the same feeling, is the characteristic of sympathy. *Personal distress*, on the other hand, is a self-directed emotional reaction, which might be a result of empathic overarousal. Hence, personal distress is related to aversive reactions and the motivation to dampen the intensity of one's own empathic arousal.

Eisenberg claimed that empathy, sympathy, and personal distress are differentially associated with prosocial moral reasoning. Several research findings indicated that empathy (Eisenberg et al., 1987; Eisenberg-Berg and Mussen, 1978) or sympathy was positively linked to higher levels of prosocial moral reasoning and/or less hedonistic reasoning concurrently (Carlo et al., 1992; Eisenberg et al., 2001; Miller et al., 1996) and longitudinally (Eisenberg et al., 1991, 1995). That is, individuals with empathic or sympathetic tendencies expressed more needs-oriented moral reasoning and less benefit-oriented reasoning. Given that empathy-related responding includes 'the apprehension or comprehension of another's emotional state' and 'feeling the same emotional experience' (only for empathy) or 'feeling of concern for other' (only for sympathy), these characteristics are considered the motives for a higher, self-reflective level of moral judgment.

As personal distress is the motive for self-oriented tendencies, it is expected to be related to hedonistic reasoning at the theoretical level (Eisenberg, 1986, 2005). However, the findings with regard to the association between personal distress and prosocial moral reasoning are contradictory. Some findings demonstrated that personal distress was negatively related to higher levels of moral reasoning (i.e., stereotypic and internalized) (Miller et al., 1996) and positively related to approval-oriented reasoning (Carlo et al., 1992). But other findings indicated no significant association between personal distress and prosocial reasoning (Eisenberg et al., 1991, 2002).

Cognitive Side: Perspective Taking

Cognitive capabilities are considered important for moral justifications (Kohlberg, 1969). For example, maturation in perspective taking and other cognitive skills (e.g., abstract thinking) has been considered to be related to age-related changes in prosocial moral reasoning (Carlo et al., 1992) such that as perspective-taking skills improve, prosocial moral reasoning also becomes less hedonistic and more other oriented, needs oriented, and internalized (Eisenberg et al., 1991, 1995).

According to Eisenberg (1986), this association between perspective taking and prosocial moral reasoning might not be very strong or consistent because the empathy or sympathy level may be a source of variation in prosocial reasoning. Eisenberg et al. (2001) found that regardless of their perspective-taking level (low, medium, or high), adolescents with higher levels of sympathy expressed more advanced levels of prosocial moral reasoning. However, for adolescents with low or moderate sympathy, the perspective-taking level was a significant predictor of moral reasoning. This interaction indicated that for individuals with lower or moderate levels of sympathy, cognitive factors contributed to higher levels of prosocial moral reasoning. Moreover, Eisenberg et al. (2001) found that cognitive perspective taking did not have a direct relation to adolescents' prosocial behavior; its relation to prosocial behavior was mediated through prosocial moral reasoning and sympathy, indicating that perspective taking has an indirect influence via either sympathy or prosocial moral reasoning. Eisenberg et al. (2001) concluded that perspective taking fosters prosocial acts only if it promotes sympathy or mature levels of prosocial moral reasoning.

Cross-Cultural Similarities and Differences in Prosocial Moral Reasoning

Cross-cultural studies in prosocial moral judgment mostly focus on the individualism–collectivism continuum. Individualistic cultures value personal goals over communal goals; and they endorse independence, self-reliance, initiative, and economic freedom more. On the other hand, group harmony, cohesion, interdependence, and obedience are the attributes valued more highly in collectivistic societies (Triandis, 1995). So, people in individualistic societies are expected to promote values of self-gain more highly, whereas people in collectivistic societies are expected to emphasize other-oriented concerns more.

Studies have revealed both similarities and differences in prosocial moral reasoning among individualistic societies and between collectivistic and individualistic cultures. The overall patterns of reasoning of German (Eisenberg et al., 1985) and Israeli children (Fuchs et al., 1986) were mostly similar to those of US children (Eisenberg, 1986). German children expressed more direct reciprocity in their moral reasoning, while American children referred to stereotypic reasoning more than did German children (Eisenberg et al., 1985). In the study of Fuchs et al. (1986), moral justifications of Israeli children were found to be higher and more diverse than those of American children. Moreover, it was shown that the responses of Israeli Kibbutz children involved more internalized values and needs-oriented aspects than did the responses of Israeli city and American children. This difference was consistent with their cultural orientation of Kibbutzim, where personal ties and contact are highly emphasized.

Cross-cultural differences in the level of moral reasoning have been noted, especially in the expression of internalized values or affective states. The frequency of this reasoning was lower in the Maisin (Tietjen, 1986) and Brazilian people (Carlo et al., 1996) compared to their American counterparts, and lower in Turkish compared to Spanish adolescents (Kumru et al., 2012). Researchers have argued that this difference between individualistic and collectivistic societies might be due to the educational system in those countries (Carlo et al., 1996; Kumru et al., 2012). It was claimed that the Westernized educational system, which encourages critical understanding and abstraction, might foster more internalized moral reasoning.

The Association between Moral Judgment and Moral Behavior

Does having a certain level of prosocial moral judgment mean that it would result in performing moral behavior such as donating, helping, sharing, or volunteering? An early review of the studies examining the relation between moral cognition and behavior highlighted that there was a positive association between them (Underwood and Moore, 1982). Eisenberg and colleagues have also demonstrated that in the preschool period, spontaneous sharing was negatively related to hedonistic reasoning (Eisenberg et al., 1984a) and positively related to needs-oriented reasoning (Eisenberg et al., 1985; Eisenberg-Berg and Hand, 1979). Other types of prosocial behaviors, including spontaneous helping and peer-initiated sharing and helping (Eisenberg et al., 1984), and helping and comforting behaviors (Eisenberg-Berg and Hand, 1979), were not associated with the levels of prosocial moral reasoning. In early childhood, donating behavior was negatively related to hedonistic-oriented reasoning and positively related to needs-oriented reasoning, whereas helping did not covary with the forms of prosocial reasoning (Eisenberg et al., 1985). In middle childhood, hedonistic reasoning was negatively related to donating behavior, and affectional relationship reasoning was positively related to helping in middle childhood (Eisenberg et al., 1984b). Helping behavior was not associated with higher levels of moral reasoning, but donating was negatively correlated with hedonistic-oriented reasoning and positively with higher levels of moral reasoning in adolescence (Eisenberg et al., 1991, 1995) and in late adolescence and adulthood (Eisenberg et al., 2002, 2013).

These findings suggest that the strength of the association between moral reasoning and behavior changes as a function of the motivations for engaging in prosocial behavior. In other words, not every prosocial behavior includes altruistic motivation, that is, self-sacrifice or genuine voluntary behavior. Eisenberg (2005) suggested that there are several motives for performing prosocial behaviors, including egoistic concerns (e.g., the expectation of reciprocity, award, or approval), practical concerns (e.g., preventing an unwanted situation or helping), other-oriented concerns (e.g., showing sympathy), and moral values (e.g., internalized values about the world and people). Egoistic and practical concerns elicit nonaltruistic behaviors, whereas other-oriented concerns and moral values promote altruistic behaviors (Eisenberg, 1986). This distinction between altruistic and nonaltruistic prosocial behavior is important in understanding the association between prosocial reasoning and acting.

Several findings indicated that sympathetic reactions and personal distress are differentially related to prosocial *behaviors* such that sympathy was correlated with higher levels of prosocial behaviors, while personal distress was correlated with lower levels of prosocial responding (Eisenberg and Fabes, 1990; Eisenberg et al., 1990; Miller et al., 1996). Eisenberg (2005) suggested that sympathy is associated with altruistic behaviors because it includes other-oriented concerns, which are likely to promote prosocial acts. However, personal distress is considered to be related to nonaltruistic prosocial behaviors because people might engage in helping behavior with practical concerns (i.e., dampening the stress level). Moreover, Miller et al. (1996) found that children high in both needs-oriented reasoning and sympathetic concerns (i.e., self-reported sadness to peer-distress) were more likely to exhibit helping behavior to distressed peers, indicating that the levels of prosocial moral reasoning and sympathy are important for prosocial responding.

In addition to different motives in prosocial behavior, situational factors also contribute to the magnitude of the relation between cognition and behavior. Eisenberg and Shell (1986) found that the cost of the prosocial behavior mediated the association between prosocial moral reasoning and behavior. In this study, children were asked to donate to poor children in two different donating occasions (the donation of high- and low-cost items). It was shown that needs-oriented reasoning was positively related to donating in high-cost situations, but the link between moral reasoning and donation was not significant in low-cost situations. Eisenberg (1986) argued that "if a given behavior is low in cost to the actor, it frequently may be performed without much cognitive reflection, moral or otherwise. Furthermore, if the benefit to the other is small, moral concerns related to other's welfare are unlikely to arise. Of course, if the price of helping is too high, there also may be little relation between moral reasoning and behavior because of limited variation in helping behavior (few individuals may help)" (p. 155).

Summary

Eisenberg's prosocial moral reasoning focuses on the justifications behind prosocial actions in more real-life conflicting situations. She suggests five levels of prosocial moral reasoning, ranging from hedonistic orientation to empathic or internalized orientation. Age-related changes in prosocial moral reasoning are evident such that lower levels are more pronounced in early childhood, whereas higher levels are common (often in tandem with lower levels) in adolescence. This change in prosocial moral reasoning is partly related with improving empathic, sympathetic, and perspective-taking skills. Finally, there is a positive association between prosocial moral reasoning and prosocial behavior, but motivational and situational factors are also important in this relationship.

Abstract

Shmuel Noah Eisenstadt was a major figure of macro- and comparative-historical sociology. His work connected the comparative study of institutions, a Weberian interest in world religions, and Martin Buber's lead on human creativity, intertwining structural differentiation and institutional analysis with a cultural-interpretative approach to the dynamics of continuity and change in historical and modern societies. He connected the study of power and institutions with the search for trust and meaning. Among his contributions are studies stressing the role of agency, structure, and culture in processes of change; a critical assessment of modernization studies; institutional and civilizational analyses, among them of Japan and Jewish civilization; and the approach of multiple modernities.

Shmuel Noah Eisenstadt (1923–2010) was one of the towering figures of twentieth-century macro- and comparative-historical sociology. In his work, which includes close to 100 books and 600 academic journal articles and book chapters, Eisenstadt brought together the comparative study of institutions, a Weberian interest in world religions and civilizations, and Martin Buber's lead on human creativity, intertwining structural differentiation and institutional analysis with a cultural-interpretative approach to the dynamics of continuity and change in historical and modern societies.

Born in Warsaw, Shmuel Noah Eisenstadt migrated to Mandatory Palestine with his widowed mother when he was young. After completing his academic studies at The Hebrew University of Jerusalem, Eisenstadt served as a Faculty member of the university in Israel from 1949 until his retirement in 1990. A worldwide academic traveler, he was a visiting professor at many other universities and research institutions, including Chicago, Harvard, Zurich, Vienna, Bern, Stanford, Berlin, and Uppsala. Eisenstadt received many awards, among them the McIver Prize of the American Sociological Association (1964), the Rothschild Prize in Social Sciences (1970), the Israel Prize (1973), the International Balzan Prize (1988), the Max Planck Award for Social Sciences (1994), the Amalfi Prize for Sociology and Social Sciences (2001), the EMET Prize in Sociology (2005), and the Holberg International Memorial Prize from the Norwegian Parliament (2006). He also held honorary PhDs from Harvard and Warsaw. Eisenstadt was a member of the Israeli Academy of Sciences, a Honorary Foreign Member of the American Philosophical Society, Foreign Associate of the National Academy of Sciences in the USA, Honorary Foreign Member at the Academy of Arts and Sciences, Honorary Foreign Research Fellow at the Institute of Sociology of the Chinese Academy of Social Sciences, and Honorary Fellow of the London School of Economics and Political Science.

A student of Martin Buber in Jerusalem, his work projected Buber's approach on human creativity into a venue of comparative-historical sociology inspired by the approach of Max Weber and comparative institutional analysis, as developed by British sociology and social anthropology. Bridging social sciences and world history, Eisenstadt stressed the interplay of social structure, culture, agency, and change. He was particularly interested in tracing the multiple ways in which human societies have confronted structural challenges while organizing power, building trust, and searching for meaning. His early work dealt with the sociology of immigration and youth from the perspective of elites, primary groups, and social differentiation. He then analyzed the political system of empires and comparative studies of modernization; the study of strata formation, charisma, and institution building. Starting in the 1990s, he increasingly moved to the comparative study of civilizations, through which he stressed the interplay between the order-maintaining and transformative dimensions of culture, and completed a transition from comparative institutional analysis to comparative civilizational analysis.

His early works were influenced by structural-functionalism, sharing its drive at systematization and its emphasis on structural differentiation, particularly as he studied processes of modernization. Yet, already at that stage in his career, he combined such emphasis with an interest in human agency and change, i.e., in the active role played by human beings in shaping their own history under conditions not of their own choice, as he used to indicate following Marx's famous statement in *The Eighteen Brumaire of Louis Bonaparte*. Increasingly, Eisenstadt broke with the premises of other studies of modernization, in which he was involved in the 1960s. In his later writings on modernization, he became highly critical of theories that expected societies to converge around a homogenous model of modernity driven by urbanization, industrialization, or secularism, supposedly replicating the model led by the 'rise of the West.' Rather, he stressed how modernization unfolded differently throughout the world as the result of multiple cultures and their different ways of interpreting and shaping human existence. While exploring processes of construction of institutions, he devoted efforts to trace the open aspects of social life, the ephemeral and contingent, the charismatic and value-laden transcendent dimensions of existence – all of which led to different constellations of power, trust, and meaning. This ultimately led him to stress the open code of modernity, while rephrasing and elaborating a systematic research program around the idea of not one, but rather Multiple Modernities.

From Generation to Generation (1956, new edition 2002) and *The Political System of Empires* (1963, new edition 1992) stand out among his early works. The former is his first broad comparative work in which he analyzed age groups and youth groups in different societies, connecting their emergence to issues of transference and transformation of trust from family and kinship groups to broader social settings. In the latter book, which gained him recognition beyond the realm of sociology particularly by creating long-lasting dialogues with historians, Eisenstadt suggested that the formation and institutionalization of empires were not automatically determined by structural differentiation but was rather contingent upon certain additional conditions. Among such conditions, he identified the development of free resources, i.e., resources not embedded in ascriptive settings, and the emergence of political entrepreneurs, elites, and coalitions able to construct imperial systems out of their internal contradictions and external processes and forces, all of which generated struggle, change, and the eventual demise or transformation of such systems. This perspective led to studies of structural differentiation and modernization, in which he likewise stressed the role of protest, fragility, and change and the possible breakdown of modernization (e.g., *Essays on Comparative Institutions*, 1965; *Modernization, Protest and Change*, 1966; *Tradition, Change and Modernity*, 1973a). Likewise, he increasingly moved to recognize how traditions shape processes of modernization and are embedded in them, a line that crystallized in his analysis of post-traditional societies (Eisenstadt, 1973b) and years later became integral to his work on multiple modernities (Fisher, 2012).

In the 1970s, Eisenstadt connected this early work with the strong criticisms directed at structural-functionalism by different approaches that gathered momentum in sociology and related disciplines. All these approaches shared an unwillingness to accept any institutional setting as given due to 'systemic needs,' thus setting the stage for controversies on the salience of structure and agency and pulling interventions that crystallized around the opposing poles of 'negotiated order' versus that of 'deep structures,' and that of culture or the symbolic dimension of human interaction versus the emphasis on material or power dimensions. In *The Form of Sociology: Paradigms and Crises* (1976, with M. Curelaru), Eisenstadt engaged in a discussion of the very construction of institutions as a central problem of sociological analysis, suggesting the need to systematically address the relations between agency and structure, and between culture and social structure. He then moved to emphasizing the autonomy of culture and individual choices as part of his reappraisal 'of the processes of reconstitution of social order' and the dynamics of social change.

The perspective of social exchange, as derived from Emile Durkheim, Marcel Mauss, and others provided a means for such reappraisal. First elaborated in *Social Differentiation and Stratification* (Eisenstadt, 1971) and in unpublished articles with E.O. Schild, in which he addressed the importance of various media of exchange, including money, power, and prestige as crucial for center formation, elite status, and stratification, he fully developed this perspective in the 1980s, particularly in the comparative work on clientelism and friendship undertaken with Luis Roniger. In *Patrons, Clients and Friends* (1984), the systematic study of interpersonal relations in different historical and contemporary societies revealed various modes in which such relations connect specific forms of resource flow and access to resources within broader forms of exchange and the structuring of trust in society. The work indicated how specific and generalized exchange can be combined in diverse ways, which then affect how social order is structured and negotiated in society, and also what countervailing social forces emerge to contest the presence of interpersonal relations such as patron–client relations or various forms of friendship. He himself considered such endeavor as part of re-examining "the processes through which social formations are crystallized" and in that sense, as somehow akin to Anthony Giddens' theory of structuration, Pierre Bourdieu's emphasis on 'habitus' and reflexive praxis, and Alain Touraine's work on social movements (Eisenstadt, 1995: 20–22). Yet, in Eisenstadt's case, the concern with social exchange was led by a comparative-historical optic and the drive to move away from reductionist approaches that often saw culture as epiphenomenal to power or economic interests. His approach is singled out by a search for identifying the ground rules of social interaction, which he saw as driven by cultural assumptions and codes, themselves anchored in diverse cosmological visions of the world.

Eisenstadt joined such inquiry into social exchange with a long-term interest in three additional venues of research. First was his interest in center formation and charisma, triggered during his postdoctoral studies with Edward Shils at the London School of Economics. Such interest matured in his studies on empires, and later on was translated into the study of comparative urbanization, undertaken together with social geographer Arie Shachar (*Society, Culture and Urbanization*, 1987) and again in his introduction to the collected articles of Martin Buber on charisma that Eisenstadt put together in 1992.

Second, was his interest in the study of intellectuals and other carriers of change, exemplified in the book co-edited with R. Graubard on *Intellectuals and Tradition* (1973) and in a more political venue in his book on *Revolution and the Transformation of Societies* (1978). Third, was his work on the sociology of knowledge, leading to the co-edited publication with Ilana Friedrich Silber of *Knowledge and Society: Studies in the Sociology of Culture Past and Present* (1988), a book stressing the recognition of humans as cognitively oriented and reflexive beings seeking to construct symbolic configurations geared to understanding and making sense of the world, and underscoring the role of diverse soteriological orientations in particular in structuring the ensuing 'worlds of knowledge' (see also Silber, 2011).

These various macrosociological and comparative institutional studies facilitated the reexamination of the relations between cultural visions and institutional patterns and between agency and historical contingency. The work on revolutions, for example, indicated that structural factors may explain the breakdown of regimes but not the specific character of such breakdowns; that is, whether the change was revolutionary or not. In order to explain revolutions, Eisenstadt suggested the need to study the combined effects of civilizational and structural conditions coming together along with historical contingencies. The above macrosociological and comparative institutional analyses led him to move increasingly toward the comparative study of civilizations.

In his view, civilizations crystallized around overall visions that entail attempts to construct or reconstruct social life according to transcendental premises. Major civilizations developed in the period which Max Weber called the era of the 'great world religions' and Karl Jaspers and others defined as 'Axial civilizations' (Eisenstadt, 1982). At the Truman Research Institute in Jerusalem, Eisenstadt drafted by the mid-1980s a comprehensive sociological approach to comparative civilizations (1986) that eventually found its way into full-fledged books such as *The Origins and Diversity of Axial Civilizations* (1986), *Civilta comparate* (1990), and *Kulturen der Achsenzeit* (1991). In the 1990s, as he retired from Hebrew University and continued working at the Van Leer Jerusalem Institute, he launched a comprehensive research program on collective identities, political order, and public spheres, conducting various discussion groups and organizing national and international seminars, among them on comparative political thought, on Islam, and on Latin America (see Eisenstadt and Giesen, 1995; Barth and Enzell, 1999; Roniger, 2011). He also combined research efforts with Wolfgang Schluchter, Björn Wittrock, Jóhann Páll Arnason, and other colleagues to engage in the comparative study of axial – and later on postaxial – civilizations (e.g., Eisenstadt, 1998, 2000; Arnason et al., 2005).

During that stage in his career he became increasingly interested in Japan as a civilization. In Eisenstadt's view, fully developed in *Japanese Civilization: A Comparative View* (1996), Japan was one of the most interesting foci of comparative analysis due to its unusual combination of a very high level of structural differentiation combined with a low degree of autonomy of its main elites, which he attributed to the fact that Japan did not experience an Axial Age transformation leading to a chasm between the transcendental and the mundane order, as typical of monotheistic, Chinese, or Buddhist civilizations. In Japan, he identified a rather unusual combination of institutional similarities and very high levels of philosophical, literary, and ideological discourse and self-reflexivity, which resemble those in Western Europe, yet came together with institutional change disconnected from ideological claims couched in transcendental, universalistic terms, as carried out by autonomous elites in other civilizations. In his analysis, Eisenstadt stressed how Japan 'subdued' as it were the strong universalistic orientations inherent in Buddhism and Confucianism and did not become accordingly "a nation carrying God's universal mission" (Eisenstadt, 1995: 29; 1996). In that context, he claimed that Japanese modernity developed by premises that were a mirror image of the religious premises underlying the development of North American civilization (Eisenstadt, 2002).

Eisenstadt also engaged in a *longue durée* study of Jewish civilization, as reflected in *Jewish Historical Experience: The Civilizational Dimension* (2004). He pointed out that, as the first monotheism that called for the reconstruction of the world, the contours of Jewish civilization resulted from the concrete circumstances of its historical experience. Such experience was especially shaped by dispersion and Diaspora and thus prone to develop simultaneously through multiple political, economic, and ecological environments and through multiple encounters with other, especially but not only Axial civilizations. Under such circumstances, tensions grew in the unique configuration of a collectivity which entailed the concomitant interweaving of universalistic and particularistic orientations and multiple contesting interpretations and confrontations, led by dynamic carriers of identity and change. In Eisenstadt's analysis, the dispersion and lack of centralized authority enabled the development of multiple arenas for the rise of relatively autonomous, even quite anarchic, 'carriers of meaning' among Jews. This also resulted in multiple definitions of Jewish collective consciousness; in the emergence of heterodoxies and sectarianism; in a high reflexivity of Jews as a marginalized minority for two millennia; and in ambivalent modes of participation of the Jews in broader civilizational frameworks, primarily in its interactions with the Christian and Islamic worlds. This, in turn, opened the way for radical changes and innovation once conditions allowed it, but also posed anew the problem of Jewish survival and continuity in modern times. In claiming this civilizational perspective rooted in Jewish historical experience and stressing that Jews were a creative part of an intense transcivilizational interaction and interreligious competition for centuries, Eisenstadt could challenge well-established alternative interpretations such as Weber's characterization of a 'pariah people' or Arnold Toynbee's view that once dispersed, they were transformed into a 'fossilized' civilization. This also allowed him to explain – against the claims of Christian theology and some strands of modern historiography – the continuity of Jewish history in spite of territorial and political discontinuity, exile, and dispersion (see Eisenstadt, 1997a; 2009).

Eisenstadt also contributed multiple articles and chapters on Confucianism, Islam, India, and other civilizations, although not in the same detail as his analyses of Japanese, Jewish, and European civilizations (on the latter see Eisenstadt, 1987). Rather, he became the comparative voice that served as a trigger of reflexivity for a wide array of historians, social scientists, and area specialists, leading to the publication of a series of books in which sociologists, historians, political scientists, and students of culture found common ground for explorations of the encounters between world history and comparative studies. Illustrative works are *The Early State in African Perspective* (1988), co-edited with Michel Abitbol and Naomi Chazan or his contributions to collective volumes such as *Globality and Multiple Modernities: Comparative North and Latin American Perspectives* (2002, edited by Luis Roniger and Carlos H Waisman, and see also Eisenstadt, 2013) in which he suggested directions of research on the various civilizations of the Americas in terms of comparative analysis and multiple modernities.

Living in Jerusalem, throughout his life Eisenstadt also contributed studies on major aspects in the development of Israeli society. From his early studies of immigrants arriving from both Western and Middle Eastern and Asian countries to his later comprehensive analyses of Israeli society and of its transformations (1967, 1985), Eisenstadt retained a deep interest in shifts occurring in Israel. Being the leading Israeli sociologist for several decades, later generations of Israeli sociologists disputed some of the premises of his approach, accusing him of projecting a structural-functionalist approach that supposedly downplayed or displaced conflicting aspects beyond its borders (see Kimmerling's (1992) assessment). Those addressing his sociology of Israeli society in critical terms usually failed to

relate to his later writings in general, and on civilizations and multiple modernities in particular. Still, even those critics recognized his contributions to the development of sociology as an established discipline connected to comparative perspectives, with macroinstitutional concerns and addressing key questions of development. An extensive interview with anthropologist Danny Rabinovich in a festschrift in his honor provides a glimpse of Eisenstadt's ability to both understand the changes underwent by Israeli society and continue contributing a critical eye on its development as well as on the challenges that the social sciences face in a small country at the semiperiphery of the world system (Herzog et al., 2007; Weil, 2010).

As indicated, in the 1990s Eisenstadt returned with new vigor to the study of modernity, albeit with a very critical reappraisal of the classical visions of modernization studies, stressing instead the multiple, open-ended, and uncertain character of modernity, as reflected in the dynamics of change, of shifting boundaries of political membership and shifting patterns of citizenship and participation. He engaged in institutional analyses of modernity and democracy (e.g., *Paradoxes of Democracy: Fragility, Continuity and Change*, 1999a). He equally devoted energies to analyze how the tensions between orthodoxies and heterodoxies were transformed in modern times, stressing that fundamentalisms are basically modern reformulations of patterns of contestation rooted in the various soteriological premises of civilizations while challenging alternative interpretations of modernity (see e.g., his book on *Fundamentalism, Sectarianism and Revolution*, 1999b). To his last works, he remained fully aware not only of the constructive dimensions of modernity, but he also emphasized the potential destructive tendencies of "barbarism lurking within the very core of modernity" (Eisenstadt, 2013: 52).

Eisenstadt's approach on Multiple Modernities was his last major contribution to comparative social research. His view of multiple modernities entailed a basic tension between seeing the expansion of modernity as "the crystallization of a new type of civilization not unlike the expansion of the great religions or the great imperial expansions in past times," while at the same time emphasizing that even as it spread to most of the world, "modernity did not give rise to a single civilization or to one institutional pattern, but to the development of several modern civilizations, or at least civilizational patterns," i.e., of civilizations which share common characteristics, but which tend to develop different, even cognate ideological and institutional dynamics" (1998: 38–40). He did not try to downplay this tension, but rather saw it as part of the basic tensions and antinomies that have developed within the program of modernity. Among these he singled out the tensions and antinomies between totalistic and more diversified or pluralistic conceptions about many of the components of that program of modernity; namely, the conception of reason and its place in human life and society and how the construction of nature, human society, and history was conceived; the place of reflexivity and active construction of society and nature; different evaluations of major dimensions of human experience; and tensions between control and autonomy or freedom (Eisenstadt, 2000, 2007). Specifically addressing the political arena, he identified tensions between constructivist approaches that view politics as the active construction of society against those accepting society as given; between the autonomy of civil society and state power; between the civil adherence to rules and the utopian tenets of modernity; and between normal and revolutionary politics, entailing Jacobin trends (1997b, 1999b). Eisenstadt stressed that it was around these tensions that the critical discourse of modernity developed in a multifaceted and ever-changing confrontation between the claims to enhance freedom and the strong tendency to control, putting modernity in general and particularly modern democratic regimes 'on endless trial,' as he used to indicate following Leszek Kolakowski's term. All this led to continuously developing new questions, potential crises, and manifold reinterpretations of modernity interwoven with different cultural agendas and different modes of connecting instrumental rationality and value rationality; in short, to the rise of multiple modernities sustaining far-reaching reformulations of the initial cultural program of modernity (see Preyer, 2012). Eisenstadt claimed that many fundamentalist and postmodern movements, even when attempting to dissociate themselves from Westernization and in some cases rejecting the Western cultural program of modernity, yet claim modernity for themselves by reinterpreting their traditions and civilizations in an ambivalent rephrasing of modernity's premises.

In terms of sociological theory, this perspective is connected to Eisenstadt's persistent inquiry into order-maintaining and order-transforming dimensions of culture, aspects he saw as closely related to the extent of mutual determination of culture, social structure, and human behavior. In his view, these two aspects are but 'two sides of the same coin.' Distancing himself from reductionist, idealist, or materialistic interpretations of social action and social structure that give primacy to studies of culture or studies of social structure, leading to an artificial dissociation between both dimensions, Eisenstadt called to reunite studies of culture and social structure. He stressed as well that culture is neither static and homogenous nor entirely open and malleable. Focusing on dissent, protest, and liminal situations, he stressed how societies become aware of the arbitrariness of any social order, and social research becomes conscious that institutions are symbolically constructed and can be affected at different historical moments, in tribal societies, axial civilizations, and in modernity. In his own words,

> No social order or pattern of social interaction can be constituted without the symbolic dimension of human activity, especially of some basic cultural and ontological visions. It is such visions that constitute the starting point for articulating the premises and institutional contours of any patterns of social interaction and especially of institutional and macrosocietal formations. Such a construction of social order, of the interweaving of social and cultural dimensions, is effected by processes of intensive social interaction and conflict among different elites and influentials and among them and broader groups and strata. Such processes are effected by coalitions and counter-coalitions of different social actors … [who promulgate] different ontological visions [and] activate various processes of control …. [T]hese very processes give rise to orientations and movements of protest, to the structuring of liminal situations, some of which may become harbingers of change. Such developments are not accidental or external to the realm of culture. They are given in the basic fact of the inherent interweaving of culture and of social structure as two constitutive elements of the construction of social order.

> … Such seeds of transformation are indeed common to all societies. Yet the way in which they grow – the concrete constellations of different liminal situations, of different orientations and movements of protest and their impact on societies within which they develop – greatly vary among different societies, giving rise to different patterns of social and cultural dynamics.
> (Eisenstadt 1995: 323–324)

The wide impact of Eisenstadt's work in general and his perspective on Multiple Modernities in particular is likely to persist in future generations. In 'S.N. Eisenstadt: A sociological giant,' Roland Robertson has called attention to traits that transformed him into a galvanizing figure of many research programs in sociology and beyond: his amazing capacity for intellectual and emotional empathy that led to an extensive range of connections all over the world and a profound acquaintance "with virtually every region of the contemporary, early modern, primal and ancient worlds" (Robertson, 2011: 304). Edward Tiryakian has defined him recently as "the major comparative sociologist of our times" (2011: 248). Willfried Spohn considered Eisenstadt to be a "major visionary for the sociological challenges of the twenty-first century," suggesting that his work will have a lasting impact on the sociology of civilizations in the context of world history as well as in the multicivilizational conception of global modernity, since he brought to fruition a multidimensional and intercivilizational methodology that stresses the internal dynamic forces of civilizations and their specific encounters, transfers, and interrelations – a challenge that is increasingly relevant for the future of humankind (Spohn, 2011). Likewise, Donald Levine has identified Eisenstadt's legacy as championing awareness to the complexities of different civilizational traditions and sub-traditions and the potentialities of intercivilizational dialogue (Levine, 2011). Central to Eisenstadt's research program since his early cooperation with Stein Rokkan (1973) has been the identification of the inner dynamism, multiplicity of contesting centers, and increasing autonomy of European institutions (Eisenstadt, 1987), leading to its worldwide projection and generation of multiple processes of contestation and new civilizational encounters and amalgams. Thus, it is almost natural that Eisenstadt's influence has been prominent in the milieu of European social sciences – and to some extent in developing countries – rather than in the USA, as reflected, for example, in an extensive presentation of his research in *Protosociology*, volume 24 ('Multiple Modernities – A Paradigm of Cultural and Social Evolution, 2007,' and also in *Protosociology*, 2009) and in the works by Plake and Schultz (1993) and Preyer (2011). In parallel, Eisenstadt's work has continued to be translated into many languages, including recent publications in Greek and Spanish, which add to previous publications in various languages, including Arabic, Chinese, Japanese, and Portuguese.

The books published in his honor are testimony to the wide range of topics and ideas that his work has generated; see in this connection the festschrifts edited by Cohen et al. (1985), Plake and Schultz (1993), Ben-Rafael and Sternberg (2005), Herzog et al. (2007) and Gazit and Yair (2010). Forthcoming books edited by Michael Sussman and Gerhard Preyer (forthcoming) and by Benjamin Keidar et al. (forthcoming) are likely to project the impact of Eisenstadt's research program on the interface of comparative sociology and world history into new fields of inquiry, including transnational politics, human rights, or the role of contingency in human history.

Elder Abuse

Jacki Pritchard, Jacki Pritchard Ltd, Sheffield, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Elder abuse, while not a new phenomenon, has gradually gained more recognition as a social problem, with terminology and definitions changing during the past 30 years. Research has tended to be undertaken in more developed countries, but cultural, social, and economic differences between societies affect how researchers, organizations, and citizens view abuse. Consequently, the findings of incidence and prevalence studies differ. Elder abuse can occur for many different reasons; it can be the result of carers' stress but there is now more acknowledgment that perpetrators of abuse can deliberately target and groom their victims.

Introduction

Elder abuse is not a new phenomenon, having existed for many centuries. Awareness about it increased during the twentieth century after two British geriatricians wrote about their patients (Baker, 1975; Burston, 1975, 1977). However, elder abuse has never had the same level of attention or interest as child, family, or domestic abuse. For many years, it remained a taboo subject for a number of reasons: the ageism that exists in some societies, older people not being seen as emotive as children, one's fear of growing old, and acknowledging that abuse could happen to oneself.

During the past 30 years, terminology has changed, with various terms being connected to the current term 'elder abuse':

- Granny bashing/battering.
- Old age abuse.
- Adult abuse (this term was introduced in the 1990s and is used for all vulnerable adults aged over 18 years, so that elder abuse would be incorporated into this term).
- Safeguarding adults (introduced in the United Kingdom in 2005 (ADSS, 2005) and includes older people).

Professionals are confronted with many practice dilemmas when working with elder abuse. It is vital that organizations in the statutory, voluntary, and independent sectors define elder abuse in their policies and also gives detailed guidance in procedures so that practitioners are clear about how and when to intervene. Training is also essential to develop safe and best practices when investigating, empowering, and supporting victims of abuse.

Definitions

The term 'elder abuse' can be interpreted to mean harm, mistreatment, or neglect and may be carried out in many different ways including definitions and then specific categories of abuse. Researchers and policymakers can define elder abuse differently, but since the beginning of the twenty-first century there has been more usage of a definition that originally was developed by the UK Charity Action on Elder Abuse but then adopted by the World Health Organization (WHO) and other important organizations worldwide that focus on the prevention of elder abuse (AEA Bulletin, 1995; WHO, 2002, 2011):

> Elder abuse is a single or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an older person. (http://www.who.int/ageing/projects/elder_abuse/en/ – accessed 16.06.13.)

This definition like many others focuses on the older person being abused by someone in a position of trust. It does not consider that an older person can be targeted, befriended, and groomed for financial or sexual exploitation by strangers, which will be discussed below. The root of this stems from studies conducted from the 1980s onward that indicated that older persons were likely to be abused by their carers and consequently carers' stress dominated that literature (O'Malley et al., 1983; Steinmetz, 1978; Eastman, 1984; Pritchard, 1990).

Another common theme in definitions of elder abuse regards the violation of human rights

> …a violation of an individual's human and civil rights by any other person or persons. (Department of Health, 2000: p. 9)

> Elder abuse is a violation of human rights and a significant cause of injury, illness, lost productivity, isolation and despair. Confronting and reducing elder abuse requires a multisectoral and multidisciplinary approach. (Australian Network for the Prevention of Elder Abuse: www.anpea.com.au – accessed 16.06.13.)

> *Violation of Human Rights* is the denial of fundamental rights e.g. dignity, freedom of speech, religion, thought, expression, or cruel and degrading treatment. (Action on Elder Abuse South Africa: www.elderabuse.co.za – accessed 16.06.13.)

Around the world, definitions of elder abuse will differ because of cultural differences; behaviors acceptable in one society may be considered abusive in another. How older people are regarded within society will also affect how people identify and work with elder abuse. There may be denial that

such a social problem exists, especially in societies that have great respect for their older citizens (Shankardass, 2009). Research has been limited in Asia, yet some countries are beginning to highlight the issues. For example, HelpAge India undertook a survey in 24 cities across 20 states in 2013 and reported that 23% of older people had experienced abuse (HelpAge India, 2013).

(http://www.hindustantimes.com/India-news/NewDelhi/One-fifth-of-India-s-elderly-abused-at-home/Article1-1076551.aspx – accessed 18.06.13.).

In Africa, elder abuse is gradually being recognized as a social problem (Mba, 2007):

> Despite their acknowledged social and economic contributions, as well as their role in traditional and cultural affairs, many older adults in Africa experience abuse and are largely excluded in socio-economic and political affairs. The processes of modernization and urbanization are beginning to erode the traditional social welfare system of Africa, the extended family. The abuse and violence against older persons and their vulnerability to financial exploitation is a key challenge faced by many African countries. Older persons, particularly women, have to care for their dying children and orphaned grandchildren. They suffer from financial hardship and social isolation thereby endangering their health (p. 230).

Regarding South Africa, Ferreira and Lindgren (2008) discuss:

> The problem of elder abuse and neglect in South Africa is widespread but the definition of abuse remains problematic. An expanded typology is needed to classify certain types of abuse reported commonly such as marginalization, disrespect, exploitation and violence (p. 91).

Research into elder abuse in some countries of the world is still very limited, whereas in more developed countries, it can be difficult to identify elderly victims within black minority ethnic groups for research purposes because they do not ordinarily access statutory services (Bowes, Avan and Macintosh 2008; Patel 2003) but in Europe may access black and minority ethnic services (Patel, 2003).

Definitions can change and develop over time as knowledge increases. For example, at one time it was thought that elder abuse had to be ongoing:

> The systematic maltreatment, physical, emotional, or financial, of an elderly person … this may take the form of physical assault, threatening behavior, neglect and abandonment or sexual assault. (Eastman, 1984: p. 3)

Later it was recognized that it could be a one-off incident:

> Abuse … causes harm to the older person, either temporarily or over a period of time. (Department of Health, 1993: p. 3)
>
> Abuse may consist of a single act or repeated acts. (Department of Health, 2000: p. 9)

It is important to have a clear definition of elder abuse but there are additional definitions (institutional abuse, stranger abuse, and domestic violence) that help further understanding of how abuse might be inflicted. Institutional abuse is defined as follows:

> Neglect and poor professional practice also need to be taken into account. This may take the form of isolated incidents of poor or unsatisfactory professional practice, at one end of the spectrum, through to pervasive ill treatment or gross misconduct at the other. Repeated instances of poor care may be an indication of more serious problems and this is sometimes referred to as **institutional abuse**. (DH, 2000: p. 10)
>
> …where the environment, practices and rules become abusive in themselves. (Decalmer, 1993: p. 59)

In this context, consideration is given to abuse in actual institutions rather than in the community, e.g.,

- Residential care home
- Day care facility
- Hospital
- Prison

Like abuse in the community, there can be perpetrators from different backgrounds. Carer's stress has been discussed at length again in regard to this type of abuse as Pillemer and Moore (1989, 1990) highlighted during the late 1980s. Care staff can become abusive when overwhelmed by having to care for residents/patients with high dependency needs (Pritchard, 1996, 2007). Other possible causal factors are

- Lack of education/training for staff.
- Staff groups/factions developing (staff groups becoming competitive).
- Ineffective management.
- Existing rules and regimes, resulting in restriction of choice and rights, e.g., having to get up at a certain time, being made to go to the toilet before meals, and not being allowed to do something.
- Poor environment/conditions (damaged furniture, old decoration, few windows, and poor ventilation).
- Low staff morale.
- Low staffing levels.
- Staff characteristics (little patience, not caring, not suited to the job, or doing it because they need employment rather than wanting or choosing to work in the care sector).
- Characteristics of residents (high dependency needs).

A key question regularly put forward is 'When does bad practice cross that fine line and become abuse?' The debate will continue just as many scandals will be highlighted in the media. But there may also be staff members who have deliberately chosen to work in the care sector to gain access to vulnerable older people, whom they can abuse. On one level, money and/or possessions can be stolen or a person can be persuaded to sign documents that transfer assets; on another level, sexual abuse can occur.

Many people visit institutions and can have the opportunity to perpetrate abuse including

- family members,
- friends,

- professionals,
- volunteers, and
- advocates.

Also, many older people in prisons can be abused by fellow inmates or prison officers. Additionally, their physical needs can be neglected (Hayes and Fazel, 2008).

Stranger Abuse – The Debate

Much has been written about the fact that older people are abused by people who they know. However, they can also be targeted and groomed by complete strangers (Pritchard, 1993). Some organizations see this as a criminal activity that is outside the definition of elder abuse. However, others see parallels with child abuse and believe that it should also be considered.

Older people can become very lonely and isolated when family and friends die, so much so that it can make them vulnerable and susceptible to exploitation. The older person may be willing to hand over money to someone to have them visit the house. Children of a very young age can be involved in this type of abuse as can groups of teenagers. Sometimes an adult will be organizing gangs of children to engage in this activity (Pritchard, 1993).

In the United Kingdom, the Department of Health introduced the definition of stranger abuse into the *No Secrets* guidance:

> Stranger abuse will warrant a different kind of response from that appropriate to abuse in an ongoing relationship or in a care location. Nevertheless, in some instances it may be appropriate to use the locally agreed inter-agency adult protection procedures to ensure that the vulnerable person receives the services and support that they need. Such procedures may also be used when there is the potential for harm to other vulnerable people. (Department of Health, 2000: p. 11)

Domestic Abuse – To Include or Not to Include in Elder Abuse

Many types of abuse are interlinked; within families abuse can happen across the generations. In the United States and Canada, a great deal of attention has been given to the concept of family violence by researchers (Straus et al., 1980; Gelles and Cornell, 1985; Gelles, 1997). Much debate over the years concerns whether domestic abuse should be considered a form of elder abuse and how it should be addressed (Ingram, 2001). It was recognized that older women could have been living in domestic violence situations for most of their married lives. More recently, domestic abuse has been acknowledged as a form of elder abuse. Research is now being undertaken regarding intimate partner violence against older women (Nagele et al., 2010). Attention has been given to the role reversal, i.e., where the male abuser becomes the victim, the typical scenario being when the man becomes dependent on the woman later in life and the woman gets her own back because she knows he can no longer physically attack her (Friday et al., 2007).

Men can also be victims of domestic violence throughout a marriage. Although not a new concept, this remains a taboo subject. Steinmetz (1978) highlighted the problem back in 1978 and as a result had her life threatened, while the controversy continued for the next two decades (Straus, 1999). When undertaking research into the needs of older women who had been abused, Pritchard (2000, 2001) was approached by male victims who wanted to disclose the abuse they had experienced. In 2007, there was a special issue of the *Journal of Abuse and Neglect* devoted to the abuse of older men (Kosberg, 2007).

In domestic situations, mutual abuse can occur where both the older man and older woman are abusive toward each other.

> Domestic Abuse is any incident of threatening behavior, violence or abuse (psychological, physical, sexual, financial or emotional) between adults, aged 18 and over, who are or have been intimate partners or family members regardless of gender and sexuality.
>
> Family members include mother, father, son, daughter, brother, sister, grandparents, whether directly related, in-laws and stepfamily.
>
> The definition includes 'same sex' partners and ex-partners (irrespective of how long they have been apart). (Association of Chief Officers of Police and National Policing Improvement Agency, 2008: p. 7)

How Victims Define Abuse

It is crucial that when developing definitions of any type of abuse, the views and opinions of victims are taken into consideration. Eight countries – Argentina, Austria, Brazil, Canada, India, Kenya, Lebanon, and Sweden – participated in the study *Missing Voices* (WHO, 2002) to address this issue. Their analysis of the major themes revealed remarkable similarities across participating countries. Older people perceived abuse under three broad areas:

- Neglect – isolation, abandonment, and social exclusion.
- Violation – of human, legal, and medical rights.
- Deprivation – of choices, decisions, status, finances, and respect.

(WHO, 2002: p. v)

Categories of Abuse

Some definitions make a statement about elder abuse that includes what some may consider categories or forms of abuse. Thus, there can be some disparity depending on how people view what actions or behaviors actually constitute elder abuse and their importance.

It is helpful for professionals and workers to have clear guidance regarding categories of abuse to work from; however, there is some overlap between the individual categories. When investigating cases of abuse, it is useful to consider on the balance of probabilities which categories of abuse have been substantiated. Policies and procedures around the world may differ in format but there is some general consensus about what constitutes abuse, i.e., what actions and behaviors may cause an older person to be physically or emotionally harmed

(DH, 2000; Payne, 2013). In England, for many years, elder abuse was considered to have just three categories:

> The systematic maltreatment, physical, emotional or financial, of an elderly person … this may take the form of physical assault, threatening behavior, neglect, abandonment or sexual assault. (Eastman, l984: p. 3)

In the early 1990s, after the Department of Health had undertaken research into elder abuse (DH, 1992), neglect and sexual were added as separate categories:

> Abuse may be described as physical, sexual, psychological or financial. It may be intentional or unintentional, or the result of neglect. (Department of Health, l993: p. 3)

Then, in 2000, a further category was added – discriminatory abuse:

> …including racist, sexist, that based on a person's disability, and other forms of harassment, slurs or similar treatment. (Department of Health, 2000: p. 9)

Around the world, it would seem that other forms of abuse are often highlighted within definitions or as stand-alone categories of abuse. For example, the WHO states:

> This type of violence constitutes a violation of human rights and includes physical, sexual, psychological, emotional; financial and material abuse; abandonment; neglect; and serious loss of dignity and respect. (WHO *Fact Sheet*, August 2011 – http://www.who.int/mediacentre/factsheets/fs357/en/ – accessed 16.06.13.)

Sometimes particular abuses are highlighted as separate categories because organizations think they are very important or particularly significant in the country concerned. Examples include

Social: such as restricting the older person's social freedom and isolating him or her from family and friends (Australia).

Witchcraft: occurs mainly in the more rural provinces of South Africa. Women, especially black women, living alone who are particularly dark skinned and wrinkled, are accused of being witches. This is usually prompted by disasters in the area, e.g., storm or lightning damage and crop failures. The victims are in danger of suffering physical harm and/or having their homes (huts) burnt down.

Systemic abuse: this is denying older persons the right to be treated with respect and dignity when accessing services, both those belonging to the state or the private sector (South Africa).

General Overview of the Categories of Elder Abuse

Physical Abuse

- Being physically attacked/hurt/assaulted with hand or implement: slapping, hitting, punching, pushing, kicking, shaking, pinching, hair pulling, spitting and burning
- Force feeding
- Restraint
- Rough handling
- Imprisonment: keeping in confined space
- Medication: overmedicating, withdrawal, hiding medication, not giving correct dosage, being given another person's medication, and not reviewing medication regularly

Emotional/Psychological Abuse

- Verbal: shouting, swearing, name-calling, misuse of names, use of nicknames, and derogatory comments
- Threats/coercion: causing fear/anguish, unjust emotional pressure
- Humiliation
- Ridicule
- Degradation
- Manipulation
- Harassment
- Bullying
- Lack of acknowledgment/ignoring
- Exclusion
- Abandonment
- Overprotection: not being allowed to do things
- Lack of social interaction/contact
- Denial of human rights

Financial/Material Abuse

- Theft
- Fraud
- Mismanagement of money/pension/benefits/assets
- Denying access to money/assets
- Taking/spending money without consent (e.g., out of the automated teller machine)
- Shopping: saying things cost more than they did
- Selling without consent: objects, assets
- Using own reward points cards for personal financial gain
- Not paying bills
- Falsifying documents
- Forgery/forcing/obtaining signatures
- Forcing transfer of money, accounts, assets
- Forcing changes to bank accounts, wills
- Blackmail
- Charging for services that should be free or are included in fees
- Abusing position of trust, especially as attorney or appointee
- Obtaining a credit card in the older person's name and using it for oneself
- Writing of wills

Neglect

- Failure to meet physical and/or emotional needs
- Act of omission: failure to do something
- Deprivation/lack of basic care
- Lack of light/heat
- Lack of food, drink, appropriate diet
- Lack of appropriate/new/desired clothing, no access to washing facilities
- Leaving older person sitting/lying in urine/feces

- Not providing appropriate accommodation/environment
- Absence of mobility aids (e.g., walking frame), movement being restricted
- Not aiding communication
- Not allowing social contact
- Lack of stimulation
- Ignoring
- Excluding
- Imprisonment, kept in confined area
- Not replacing essential items (e.g., batteries for hearing aid, ill-fitting dentures, and old/broken spectacles)
- Denying access to services (e.g., medical/health/community) when needed
- Not providing transport
- Not providing access
- Not providing information/education/options in order to make choices
- Not assessing/reassessing when needs arise or change
- Religious/spiritual/cultural needs not being met

Sexual Abuse

- Being forced into sexual activity without consent
- Penetration of mouth, anus, or vagina (with finger, penis, object)
- Indecent assault
- Rape
- Incest
- Inappropriate touching/kissing/fondling
- Inappropriate/sexualized language or conversation
- Masturbation: being forced to masturbate or to watch someone else
- Sexual harassment
- Pornography: forced to engage in, look at magazines, watch digital video disc
- Exposure
- Voyeurism
- Prostitution
- Sex trafficking
- Bestiality
- Ritual/satanic abuse

Discriminatory Abuse

- Making discriminatory/derogatory comments
- Harassment
- Hate crime: attacks on person/property
- On grounds of age, gender, race, culture, religion, sexual orientation, or disability not allowing access to:
  - a place
  - a service
  - treatment
- Forced marriage
- Honor Based Violence

Incidence and Prevalence

Researchers' and organizations' differing definitions of 'abuse' can affect the statistics presented in incidence and prevalence studies and the way in which people work with victims and abusers (including which cases they will/will not take on). Studies may also differ regarding the age of an 'older' person. Organizations working with older people can define old age as 50, 55, 60, 65 years or more. These differences cause problems in estimating how much elder abuse is being perpetrated. Also significant is the large amount of underreporting for various reasons. An older person may feel shame or embarrassment that someone close to them is harming them. Victims may love their perpetrator and choose to stay in the situation, although they may want the abuse to stop because maintaining their relationship with the perpetrator is more important than leaving or doing something about it. They may feel that no one will believe them if they disclose abuse. The victim may have a communication problem (e.g., physical disability – deafness, speech impairment after a stroke, or a learning disability) or a cognitive problem (dementia: brain injury) that could impede disclosure. An older person living in a care setting may be scared to speak out, fearing reprisals from staff caring for them. Workers themselves may not report abuse they see perpetrated by colleagues because they need their job and do not want to be considered whistle-blowers.

Researchers can face a range of problems when conducting studies (either quantitative or qualitative): developing definitions, gaining access to agencies, and identifying victims to obtain data. It is still useful to read some of the early prevalence studies (Finkelhor and Pillemer, 1988; Podnieks and Pillemer, 1990; Podnieks, 1992; NCEA, 1998) alongside more recent ones (Naughton et al., 2012; Lifespan of Greater Rochester, Inc., 2011; O'Keeffe et al., 2007; NCEA, 2006; Eisikovits et al., 2004; Teaster and Otto, 2007). Prevalence figures vary significantly – from 1 to 10% (Lachs and Pillemer, 2004), making actual rates for prevalence and incidence unclear.

The incidence and prevalence of elder abuse may remain unknown for the following reasons:

- Inconsistency in defining what constitutes abuse
- How statistics are collated
- Differences between countries (cultural): how society and the victims see abuse
- Underreporting because of fear of the abuser, the repercussions, not being believed, shame, and embarrassment.

Despite the vast literature on the quality of care in institutions, no global prevalence or incidence data are available. A survey of nursing home personnel in one US state disclosed that 36% of nursing and aide staff reported having seen at least one incident of physical abuse by other staff members in the preceding year and 10% admitting to having committed at least one act of physical abuse themselves. At least one incident of psychological abuse against a resident was observed by 81% of the sample and 40% admitted to committing such an act (Pillemer and Moore, 1989, 1990). The lessons from this are that all organizations should have whistle-blowing policies in place together with training programs that encourage the reporting of abuse.

Practice Issues and the Law

> …elder abuse is an issue to be considered in all domains of social work practice. Intervention in cases of elder abuse is often fraught with ambiguity and ethical dilemmas as the application of professional principles is less than straightforward, bringing to the fore personal, legal, and ethical concerns in the management of the client's safety and well-being. (Donovan and Regehr, 2010: p. 174)

Practice dilemmas can occur for anyone working with a victim of elder abuse. To promote best practice, workers need knowledge, time for reflection, and experience in dealing with cases. Comprehensive training programs need to be developed so that workers are clear about: what constitutes abuse (acknowledging cultural differences), how to identify and investigate abuse, and how to support a survivor of abuse in the long term. Adequate funding is required to improve professional support and interventions. Working with elder abuse is very different from child abuse because adults have the human right to live their life as they wish. Therefore, it is important to listen to and empower a victim. Workers may recognize that an older person is at risk of harm but she or he chooses to remain in that situation or the victim contacts an agency for help but then refuses to accept services (Linzer, 2004).

Key questions for continued debate concern:

- Mandatory reporting
- Statutory intervention
- Promoting self-determination
- Breaking confidentiality

Adults have human rights to live their life as they wish and the capacity to make decisions (including unwise ones) for themselves unless proven otherwise. However, there will be some older people who become vulnerable and susceptible to abuse because they lack mental capacity regarding some aspects of their life and may need protection. The law covers two main issues regarding abuse: whether there should be mandatory reporting of abuse and whether there should be specialist legislation to protect vulnerable adults. Many abusive acts are crimes and so practitioners across the professions should be aware of the criminal law that needs to be adhered to and utilized. However, some policymakers believe that elder abuse should not be criminalized and a welfare model should be followed (Bennett and Kingston, 1993; Mellor and Brownell, 2006; Nerenberg, 2008).

In certain parts of the world, specialist laws have been developed to protect adults, which include older people. For example, in Scotland, three civil statutes were introduced to form the legal framework for inquiry, assessment, and intervention (Mackay, 2008):

- Adults with Incapacity Act (Scotland) 2000
- Mental Health (Care and Treatment) (Scotland) Act 2003
- Adult Support and Protection (Scotland) Act 2007

Legislation that protects an older person who is being abused will usually cross different parts of the law: criminal, family, or civil. In the United States, older people are protected by federal and state statutes (which differ from state to state) under three categories of law:

- Adult protective services
- Institutional abuse
- Long-term care ombudsman program (Steigel and Klem, 2007).

In Canada, four main types of law cover elder abuse cases:

- Family violence laws
- Criminal law
- Adult protection laws
- Adult guardianship laws

In the province of Quebec, human rights legislation can also be used (Canadian Network for the Prevention of Elder Abuse www.cnpea.ca/canadian_laws_on_abuse_and_negle.htm#) – accessed 16.06.13.

Japan has introduced a specific elder abuse law – the Elder Abuse Prevention and Caregiver Support Law (April 2006) – which:

1. Legally defines and categorizes elder abuse for the first time.
2. Clarifies the responsibilities of national and local governments, designating the municipal government as the central agency in charge of elder abuse prevention.
3. Establishes the mandatory reporting system for both domestic and institutional abuse cases.
4. Emphasizes the importance of caregiver support (Watanabe, Y., International Longevity Center Japan, http://longevity.ilcjapan.org/t_stories/0703.html – accessed 16.06.13.).

A study concerned with the impact of the law concludes "it was a significant step in reporting systems and activities for increasing awareness among service providers. Further policy should address how to establish intervention teams and multi-agency networks, how to conduct home visits to investigate reports, and how to approach cases resistant to outside support." (Nakanishi et al., 2009, http://www.ncbi.nlm.nih.gov/pubmed/19041151 – accessed 16.06.13.)

In developed countries, policies, procedures, and guidance exist for organizations regarding how to prevent, report, and investigate cases of elder abuse. This is often seen as a social problem with social care agencies taking the lead in conjunction with the police. In Britain, the review of the Department of Health's guidance *No Secrets* considered whether the police or social services should take the lead in future: "The Police Service believed that national leadership should lie with Adults Social Care, while the Department of Health and, on a local level, felt responsibility should sit with Safeguarding Adult Boards." (DH, 2009: p. 7)

Conclusion

Progress is being made around the world in dealing with elder abuse. However, governments and organizations across the statutory, voluntary, and independent sectors ought to continue to raise awareness about the issue. Everyone needs education about how prevalent the problem is, who might

become a victim, who perpetrates harm and mistreatment, why this might happen, and where it occurs. Preventative work should be ongoing, while policies, procedures, and guidance should be in place for anyone working with an older person.

Elder Care

Mary P Sullivan, Brunel University, Uxbridge, UK

Abstract

Both increasing life expectancy and declining fertility rates across the globe mean that by 2045 the number of older people will exceed the number of children. The implications of population aging are made more complex by diverse family structures, disease, and disability, particularly for the oldest old, and slow economic growth. The management of these and other consequences impact upon social work's participation and contributions to interdisciplinary approaches to elder care. Adopting person-centered approaches to care, social work promotes citizenship; dignified care to minimize the impact of transitions, decline, or disability; and protect the most vulnerable.

Introduction

Health and social care for an aging population is drawing increasing attention around the globe. This article discusses social work's contribution to elder care. It briefly sets the context for gerontological social work by reviewing the changing global demographic profile, introduces social and economic policy considerations that directly impact on how care is delivered, and characteristic health and social care needs of older people. Social work's key roles in assessment of need, care management, and therapeutic interventions are then reviewed to draw attention to the profession's contribution to intervening in and facilitating caring environments for older people with complex and changing needs. Finally, gerontological social work's capacity to address the needs of an aging population is considered and recommendations for further development made. This article draws on practice examples from various countries, but a thorough cross-national analysis is beyond its reach.

Setting the Context for Social Work with Older People

Population Aging

The world's population is aging. Both increasing life expectancy and declining fertility rates in the global north and south means that by 2045 the number of older people will, for the first time, outnumber the number of children. The global percentage of people over the age of 60 years is expected to rise from 11% in 2009 (700 million) to 22% in 2050 (2 billion). And while the global north has already experienced the impact of a transformed age structure, the growth of an aging population is far greater in the global south and these countries are expected to draw level to the global north by 2050 (UN, 2009). The resultant dependency or potential support ratio is what concerns nations about how they will respond to these challenges as the size of the working-age population (16–64 years) shrinks in relation to the increasing size of the dependent or nonworking population (65 years or older). In 2009, there were nine potential workers for every person 65 or older. By 2050, this is expected to change to four workers for every older person (UN, 2009). While countries around the globe are exploring ways to extend older people's participation in the workforce, relatively little is known about older worker health and well-being, the feasibility of an older workforce in varied work environments, or the larger scale social and economic impacts of extending working lives (Bossaert, 2012; Kalache et al., 2005). Thus, the far-reaching social, political, and economic impact of this 'demographic transition' is unprecedented and presents important opportunities and challenges for all nations.

The implications of population aging are both complex and numerous, and have substantial relevance for social work. Some key issues are highlighted here to enhance the critical lens that social workers adopt and that contest the social construction of ageing as a 'problem.' First, the provision of social support for older people within the family is being confronted by a reduction in intergenerational assistance and/or filial piety as family size reduces, as women engage in work outside the home, and as children migrate for employment (Silverstein and Giarrusso, 2010). Second, as people live longer beyond retirement and the working-age population shrinks, the current levels of provision of health and social welfare, including pensions, are no longer economically sustainable and ultimately demand radical transformation (Bossaert, 2012; Marshall and Taylor, 2005). In the global south where welfare structures remain scarce, the prospect of any formal care system significantly diminishes despite need (e.g., less informal care exchanges due to declining fertility rates) (Kalache et al., 2005).

Third, the fastest growing segment of the population is people over the age of 80 years (UN, 2009). The World Health Organisation (2004) reported that 46% of people over the age of 60 years were living with moderate to severe disability, and levels of disability were higher in low- to middle-income countries. This percentage gradually increases with age, for example, 55% of people aged 85–89 years are disabled and 90%of people aged 95–99 years are disabled (Poon et al., 2005). Poon et al. (2005) estimate that one-third of the oldest old are able to live independently despite health conditions, one-third are functionally impaired, and one-third are either extremely frail or disabled. While disease in the global north is commonly associated with cardiovascular and respiratory disease and cancer, it is worth noting the number of people

who will experience dementia is likely to increase. The World Alzheimer Report (2010) projects the number of people across the globe who will be affected by dementia will reach 67.5 million by 2030.

Policy Context

The current global financial crisis has had a dramatic impact on policy direction as countries grapple with economically and socially viable alternatives to support a population that is still commonly viewed as a burden. These demographic fears (Mullun, 2000) easily contribute to the oversimplification of an ideal solution to what is otherwise very complex and do little to tackle issues such as ageism in health and social care structures and/or intergenerational tensions. For example, the concern about health care costs due to the expansion of morbidity fails to consider health inequalities earlier in life. Older people who engage in either paid or charitable work beyond typical retirement age do not confirm society's construction of dependency. And, grandparents who provide care for grandchildren while the middle generation pursue careers fail to corroborate the absence of thriving interdependent relationships and informal social exchanges.

The United Nations Madrid International Plan of Action on Ageing (MIPAA) (2002) identified three priorities to assist governments and other nongovernmental organizations to "reorient the ways in which their societies perceive, interact with and care for their older citizens" (UN, 2012: p. 5). These priorities included (1) older people and development, (2) advancing health and well-being in older age, and (3) ensuring enabling and supportive environments. While these priorities may be realized in individual countries, the essential thrust is promoting social inclusion, economic security, good health, and safe and accessible environments. The International Federation of Social Work's (IFSW) 'International Policy on Ageing and Older Persons' (2009) drew on the MIPAA to translate salient implications for social work around the globe. Briefly, the IFSW acknowledges social work's strategic position to enable the full social integration of older people. This includes promotion of their social, economic, and intellectual contributions and considered macrolevel and microlevel advocacy to tackle any social conditions that hinder security, health, and well-being (Hokenstad and Roberts, 2011).

While a genuine commitment to pursue these objectives was likely given by the nations involved, no one could predict a global financial crisis and subsequent contraction of welfare programs (including pensions) in so many countries, or persistent political instability and conflict in others. Such an environment does not bode well for those who are already marginalized or disadvantaged due to socioeconomic inequalities. Policy makers, however, have to make choices.

Alongside the principles embedded in the MIPPA, the concepts of active, healthy, or successful aging have become familiar in Western policy discourses. More recently, the term active aging has taken a stronghold in global social policy as a means of enhancing quality of life as people age. The principles broadly promote activity throughout the life course as a protective measure from decline and isolation, and activity in later life as a means to encourage pursuits that contribute to well-being, family and community engagement and participation, intergenerational solidarity, and respect for diversity (Walker, 2009). However, active aging easily leads policy makers into a quagmire, given this cannot be achieved by individual effort alone. Determinants of health unequivocally draw attention to the role of structural or contextual factors in optimizing good health or quality of life at any age (Holstein et al., 2011; Lloyd et al., 2013). In the event that a poor economy only permits a very conservative or tentative reform of welfare to support active aging, it follows that it becomes an individual responsibility to age well. For those who are very old and unavoidably dependent, further marginalization denies them an authentic caring environment (Boudiny, 2012; Holstein et al., 2011).

Health and Social Care Needs of Older People

A diverse range of biological, psychological, and sociological theories of aging provide the backdrop for understanding the determinants associated with longevity or decline, psychological development in later years, and the experience of being old. While this is the lens by which researchers have come to understand older age, the purpose here is to present what is commonly understood in relation to health and social care problems, given their consequences are directly relevant to social work practice.

Nevertheless, in the social sciences, the life course perspective has become integral to understanding how human lives are intimately linked to and embedded within historical events, social and cultural institutions, and technological advancements (Green, 2010). To briefly elaborate, the principles of this perspective progress an understanding of how lives may take different paths, despite similar events, and the ever-constant tension between continuity and change over the life course. Thus, age and its various meanings are lifelong processes that are situated within (1) an individual's interconnectedness with others, (2) historical time and place, (3) transitions and their timing, and (4) individual agency (Grenier, 2012). Moreover, the utility of the life course perspective also lays in its recognition of "blurred and ragged transitional periods rather than clear-cut ages and stages" (Green, 2010: p. 24). Accordingly, this lens is particularly applicable in social work, given its person-in-environment orientation and attention to lifelong development.

Physical and Mental Health

Gradual physical changes to the body are a normal part of ageing. People tend to 'slow down' as a result of changes in bones, skin, muscle, and circulation, resulting in energy levels, flexibility, and strength that may be lesser than in earlier life. For many, these normal changes are accompanied by some form of disease and disability, which will affect an individual's quality of life. Disease and disability develop from a complex combination of intrinsic or extrinsic factors such as genes, environment, behavior, and lifestyle and access to health care (Victor, 2010).

Good health, or the absence of disease or illness, is commonly viewed as central to maintaining quality of life in older age (Victor, 2005). For older people, however, there is a tendency to evaluate their health and well-being using much broader criteria such as their ability to perform normal roles and responsibilities (Ray and Phillips, 2012). From a health care cost and provision perspective, the aim is to minimize those factors that cause mortality and morbidity. These factors will vary between and within countries owing to the various determinants of health associated with socioeconomic and political conditions (Victor, 2005), or what is commonly referred to as accumulated advantage or disadvantage. Determinants of health are reflected in the leading cause of death in various countries. For high-income countries, Eurostat (2009) lists the major cause of deaths for those aged 65 years and older as ischemic heart disease, cerebrovascular disease, diseases of the respiratory system, lung cancer, and colorectal cancer. For lower income countries, the overall leading causes of death include coronary heart disease, lower respiratory conditions, human immunodeficiency virus/acquired immunodeficiency syndrome, perinatal conditions and stroke, and other cerebrovascular conditions (WHO, 2008).

For older people, it is not uncommon to cope with comorbidity (i.e., conditions occurring because of a leading disease) or multimorbidity (i.e., simultaneous existence of several conditions). Common chronic problems include cardiovascular disease, diabetes mellitus, chronic obstructive pulmonary disease, asthma, arthritis, and unipolar depressive disorders (Pomerleau et al., 2008). While there is some support that morbidity is being compressed to fewer years before death (Freedman et al., 2002), the picture is complex and some would suggest that there may be more older people living with disability longer (Lafortune et al., 2007).

The growing number of older people with mild or severe mental health problems reinforces the complexity of health problems in this population. Similarly, as care continues to be delivered using community-based approaches, innovative models of support are required to respond to the new challenges and the impact of long-term inequality, stigma, and disempowerment (Sullivan et al., 2004). Approximately one in five people over the age of 65 years experience a mental health problem. This includes dementia, depression, psychosis, bipolar disorders, schizophrenia, and anxiety disorders (Jeste et al., 1999). Prevalence rates in institutional care are of greater concern and it is estimated that 80% of all residents are experiencing depression or behavioral disturbances as a result of dementia (Brodaty et al., 2003).

Equally disabling, but often overlooked, is sensory loss. In the United Kingdom, for example, 6.4 million people aged 65 years and older have some form of hearing loss. Almost 700 000 are considered to have severe or profound loss (Action on Hearing Loss, 2011). According to the Royal National Institute for the Blind (2012), of the 2 million in the United Kingdom with sight loss, 80% are over age 60 years. And while for many this is an anticipated feature of their older age, sensory loss can lead to depression, low self-esteem, and social isolation (Stuen, 2006).

The impact of health conditions on an older person's daily living activities, the person's ability to manage associated risks (e.g., falls and drug reactions), and his/her individual and family life (i.e., participation, adjustment, and caring) have key relevance for social work practice. The management of these and other consequences of aging and older age also have relevance for social work's contribution to interdisciplinary approaches to elder care.

Social Care and Support

The heterogeneity of the aging population reinforces the necessity to adopt a person-centered approach to social care and support, given that gender, family status, social class, ethnicity, occupation, life history, and health and disability directly influence an older person's ability to manage change and transitions at this stage in life. In addition to the possibility of disease and disability, this stage may be characterized by changes in identity, roles, family structure, and loss and stress. The features of someone's life course and the impact of, for example, the loss of a spouse, becoming a grandparent, or living in poverty will also be affected by an individual's access to intrapersonal, interpersonal, and external resources. Thus, the older population are not easily categorized as being independent or dependent.

Social workers often intervene to coordinate an older person's natural support systems and bolster these with external supports if necessary. Social work's expertise in this area tends to focus on minimizing vulnerability or risk by the provision of practical support at home. In this role, the practitioner may work with communities to cultivate relationships and supports, and with individuals to balance "conflicting needs and aspirations, working creatively with risk, seeing to preserve autonomy, and working with systems with diverse and contradictory opinions and views" (Ray and Phillips, 2012: p. 7).

Critical Gerontological Social Work Practice

Professional social work is uniquely positioned, usually as part of interdisciplinary teams, to provide a valuable contribution to well-being in later life through its leadership in relation to psychosocial issues and holistic approaches to problem solving and intervention. As Kaplan and Berkman (2011) have argued, social work values, skills set, and resources, and roles that span across a variety of organizations, enable practitioners to provide assessment and supportive, therapeutic, and educational services to individuals and their families.

Social work's contribution also extends much further. Foremost, older service users highly regard social work's involvement in the process of obtaining guidance and assistance (Beresford et al., 2011). Research by Manthorpe et al. (2007) found that "… social workers' knowledge about specialist services, persistence, commitment, reliability, and being supportive, sympathetic and prepared to listen" was repeatedly identified as essential in the helping process. Given the prominence of the social and person-in-environment perspective within the profession, social work recognizes individual need as located in the broader social context. Extending far beyond the biomedical model, individual need and/or threats to well-being are considered in relation to rights and citizenship and how an individual's life experiences are shaped by structures governing society. Social work has the capacity, when bureaucratic systems

so easily exclude vulnerable older people, to engage in advocacy and empowerment work to ensure older people have the right to make choices, the right to control their own lives, and the right to high-quality care (Hokenstad and Roberts, 2011; McDonald, 2010; Lloyd, 2006) and ensure that systematic discrimination does not deny any older person an enabling environment (Hokenstad and Roberts, 2011). Social work's role then naturally extends to strategically positioning itself to influence policy and system development.

Assessment

Using a combination of a biopsychosocial and strengths approach, a social worker characteristically adopts an assessment of need that systematically considers functioning in the following domains (Ray and Phillips, 2012; Nelson-Becker and Sullivan, 2012; Mellor and Lindeman, 1999):

1. Physical – medical history, medications, functional abilities, appearance, behavior, and substance use
2. Psychological – personality characteristics, identity, affect, and cognitive functioning
3. Social – family structure, other relationships and support networks, social roles, occupation, financial status, leisure, and community engagement
4. Environment – living conditions, risk and vulnerability, and degree of independence within the environment
5. Cultural – values, beliefs, communication, and patterns of interaction within cultural domain
6. Spiritual – religion, personal meaning and purpose, life aspirations, wholeness in relationships, and self-determination

Social workers may use standardized measures during the assessment. In specialized services such as mental health, for example, social workers may use measures to screen or narrow down the possible problem, assist in care planning, communicate assessment outcomes to other professionals, determine an optimal setting for care, or evaluate the outcomes of interventions.

The 'process' of the assessment is as important as the assessment itself. Typically grounded in a problem-solving approach, a social worker has a significant amount of power to direct the assessment and its procedural aspects and identify agency or professionally determined outcomes versus service-user choices (Sullivan, 2009). To moderate professional power and control, particularly problematic when service users are frail or cognitively impaired, a social worker must adopt a critically reflective approach. In addition, a social worker makes use of effective communication skills to cultivate a rapport with an older person and ensure their full participation (Harwood, 2007). Furthermore, the social worker simultaneously negotiates questioning and information giving, the involvement of significant others for additional data (e.g., family caregivers), and the handling of difficult or complex individual systems (Ray et al., 2009; Geron, 2006).

Care Management and Therapeutic Interventions

Following the outcomes of the assessment process, a social worker's role varies depending on the agency and the nature of the services provided – for example, community-based services, acute care, hospice, mental health or substance abuse settings, prisons, and nursing homes. Generally speaking, gerontological social work interventions are "directed at enhancing dignity, self-determination, personal fulfilment, quality of life, optimal functioning and ensuring the least restrictive living environment possible" (Mellor and Lindeman, 1999: p. 3). More recently, intervention research has contributed to a growing body of evidence of effectiveness to inform the design and delivery of psychosocial interventions (Cummings and Kropt, 2009; Burnette et al., 2003).

Familiar in the European Union, support planning and care management play the key role in community-based gerontological practice. Under the guise of community-based rather than institutional care, care managers act on behalf of government to carefully administer welfare resources for those who meet clearly defined eligibility criteria (Sullivan, 2009; Lymbery, 2005). Usually focusing on disability and dysfunction, the core functions in this model of delivery involve both the development and coordination of a support plan, access and linkage to a variety of resources (e.g., home carers, meal on wheels, transport services, and financial or legal assistance), and regular monitoring for changes (Ray and Phillips, 2012; Naleppa, 2006). Personal safety and security are also essential considerations. In the United Kingdom, recent legislation has strengthened a push toward individual or personal budgets whereby need is translated into a carefully calculated budget that is then transferred to the service user for purchasing and managing their own care (Carr and Robbins, 2009).

Not surprising, this model of practice is highly criticized. Its administrative rather than therapeutic approach has reduced social work to rationing agents who construct need as stable and treatable (Lymbery, 2012). Decision making is undoubtedly justified using discourse that places autonomy and independence as essential for all older people. A life course or person-in-environment approach is inconsistent with this system, thereby further reducing opportunities for social work intervention. Older people with complex and changing needs (i.e., those in greatest need) and the development of humane and interdependent caring environments are unfortunately abandoned (Lloyd, 2010; Sullivan, 2009).

Social workers positively engage in therapeutic models of intervention focusing on many of the critical challenges that older people encounter such as health issues and end-of-life care, mental health problems, and social roles (e.g., grandparents raising grandchildren). There is a range of theoretically and research-informed intervention approaches for individuals, families, groups, or communities. It is not possible to elaborate on all developments in evidence-informed gerontological practice here, but it is worth noting a few examples to demonstrate social work's contribution.

According to Arthritis Research UK (2008), more than one-third of the population over the age of 50 years have pain that interferes with normal activities of daily living. Its impact can be far reaching and include limited mobility, isolation due to restricted activities, and feelings of despair. Cognitive-behavioral and psychoeducational interventions are widely used, given their cost, effectiveness, and flexibility, to increase coping skills, reduce emotional distress, and maximize self-care

behaviors (Yoon and Doherty, 2009). The effectiveness of cognitive-behavioral and psychoeducational interventions for depression and anxiety disorders (McInnis-Dittrich, 2006) and substance abuse (Cummings et al., 2009) is also well documented.

Psychosocial problems as a result of dementia are also common at all stages of the disease. Gerontological social workers are involved in supporting the older person and his/her family and/or caregivers. Personality and mood changes and decline in functional abilities may cause increasing levels of stress and strain (Judge et al., 2009). Support or mutual aid group interventions for family caregivers are commonly provided. A mixed range of evidence suggests effectiveness using psychotherapeutic, cognitive, or problem-solving approaches to manage stressors (Ray et al., 2009; Greene and Riley, 2006). A variety of interventions with individuals with dementia are also being used by social work with varying levels of evidence of effectiveness to reduce the negative impact of illness-related stressors and improve quality of life (Kaplan and Berkman, 2011). Specifically, reminiscence and life review appear to provide successful approaches that are also flexible, cost-effective, and nonstigmatizing (Ray et al., 2009; Lai et al., 2004). A variety of approaches to reminiscence and life review are available. However, the essential thread is the use of memories to explore events, unresolved issues and conflicts, and inner strengths to build a positive sense of control and self-efficacy (Ingersoll-Dayton and Bommarito, 2006).

Social Work's Capacity to Respond to the Needs of an Aging Population

Social work's leadership in systematically addressing the breadth of age-related issues ranging from age discrimination and socioeconomic disadvantage to complex co-morbidityor multimorbidity and elder abuse requires continual progress to keep pace with rapid social change and the correlate ethical problems that arise. Yet, the social work profession, as a whole, has long overlooked the needs of an aging population (Sullivan, 2009). According to Kaplan and Berkman (2011), 4% of social workers in the United States have a geriatric specialism but 81% of social workers are working with older people. Social work education has not championed gerontological practice and social work intervention research has not kept pace with an increasing number of older people with complex needs. Evidence from a variety of countries continually reveals that social work students do not give preference to future practice with older people (Richards et al., 2013). As previously described, the IFSW's policy on aging and older people outlines social work's responsibility to respond to global aging and is testament that it is time to invigorate the profession's capacity to take action.

High-profile gerontological social work initiatives are occurring in North America. Since 1999, the Geriatric Social Work Initiative (GSWI), funded by the John A. Hartford Foundation in the United States, collaborates with various social work programs and organizations to raise the visibility and desirability of gerontological social work and prepare the profession to deliver high-quality care (GSWI, 2012). The GSWI's three related programs have transformed social work with older people in the United States. The Scholar's Program trains academic champions to teach future generations of social workers and engage in cutting-edge research with the Doctoral Fellow Programs, which recruit doctoral students to sustain leaders in teaching and research. The National Centre for Gerontological Social Work is 'gerontologizing' education by embedding gerontological competencies in the curriculum and thus ensuring the workforce is prepared for practice. Finally, the Hartford Partnership Program for Aging Education is developing models of field education, including the dissemination of new knowledge into the practice arena (GSWI, 2012).

Canada's National Initiative for the Care of the Elderly (NICE), founded in 2005, is a nonprofit charitable organization and social work–led network of researchers, practitioners, and students committed to improving care for older people. Initially funded by the Canadian government, the approach here is to bring research to practice and is purposively interdisciplinary owing to the research evidence that suggests best practice in geriatric care is interdisciplinary. Its three goals include to (1) help close the gap between evidence-based research and actual practice; (2) improve the training of existing practitioners, geriatric educational curricula, and student interest in geriatric care; and (3) effect positive policy changes for the care of older people (NICE, 2012). Using a series of themes (e.g., dementia care, end-of-life care, elder abuse, and caregiving), teams review the research evidence to develop and disseminate user-friendly interdisciplinary practice tools (paper and digital). NICE is currently undertaking a large-scale evaluation of the format and effectiveness of their tools (NICE, 2012).

Gerontological social work in other countries around the globe does not appear to be supported by a formal agenda for development. In the European Union, for example, welfare delivery and approaches to social work vary from country to country. Very generally speaking, social work is typically government funded, although it may be delivered by nongovernmental organizations. Private social work delivery such as that found in North America is not a trend. Practitioners assume the role of care manager or coordinator of care provision in the home – family care, private care, and state care (Soderberg et al., 2012; Crossland, 2008). In this primarily administrative model of practice, social workers have become agents charged with rationing and prioritizing state-funded support (Topo, 2011; Phillips, 2006). However, in some states in the European Union, it seems that social work has found a strong footing in areas of service-user empowerment and participation, promoting citizenship and advocacy, and playing a role in integrating health and social care systems (Emilsson, 2009).

In Australia, social work with older people appears to align itself with a more therapeutic model with various roles beyond that of care management. However, here too, practitioners tend to view gerontological practice as routine and unfulfilling (Ozane, 2006; Hughes and Heycox, 2005). These social workers are practicing in the community, hospitals, geriatric mental health teams, and dementia and end-of-life care. Private practice is also flourishing in areas such as the management of major life transitions and intergenerational

family conflict. Despite social work's visibility in these settings, Ozane (2006) urgently recommends an articulated gerontological action strategy to strengthen education and training, research capacity, and leadership.

China has witnessed an unprecedented rate at which the population is aging. The approach to care remains largely traditional in that care of older people is a normative family duty. Filial piety deeply penetrates all aspects of society, and no less is it felt than in the political realm as alternatives are considered to mitigate the effects of longer life expectancy, smaller extended families, migration, new market economies, and so forth (Xu and Chow, 2011; Chi, 2006; Zhan et al., 2006). In mainland China, social work is delivered primarily by civil society, nongovernmental organizations, and the private sector (Chi, 2006). The two key developments appear to be the growth of institutional care and various community-based initiatives to supplement family care. Preferences appear to be those that permit the older person to remain at home. Generating funds from a variety of sources (e.g., individual and corporate donations and government sources), meal programs, self-help groups, day centers, in-home care, and recreational programs are flourishing (Xu and Chow, 2011). Social work's direct contribution in these newer developments appears to be community-based practice. However, Chi (2006) states that gerontological social work is urgently required to address the psychosocial well-being of older people and their families, advance indigenous evidence-based interventions, and contribute to interdisciplinary approaches to care.

Conclusion

The implications of an aging population across the globe are numerous. All nations and their citizens are being confronted with both slow-moving economies and an increasing number of older people with complex needs. The subsequent challenges for elder care in social work are layered in social and economic policies, the competent provision of care management and therapeutic interventions, education and research, and the profession's ability strategically to interact with social institutions to remove the barriers for the creation of inclusive, caring, and enabling environments.

The aging population is diverse. Individual life course patterns are accumulated in later years and reflected in health and social care needs and a person's ability to draw on resources for support. The meaning of aging and older age is also experienced within particular contexts that may contribute added burden. Thus, person-centered approaches to care are necessary to promote citizenship; dignified care to minimize the impact of transitions, decline, or disability; and protect the most vulnerable.

More recently, critical gerontological social work initiatives have articulated the profession's unique contribution to supporting older people and their families. Practice is characterized by both macro- and microlevel engagement, specialized skills to address complexity and co- or multimorbidity, evidence-informed interventions, and high-level commitment to working with systems to encourage ethical responses to constraining features in contexts of practice. Social work is about working with those who are not privileged to foster human flourishing and supporting individual capabilities. For critical gerontological social workers, the time is now for compassionate thinking and considered responses.

Elections: Apportionment

Bernard Grofman, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Apportionment refers to the determination of the number of representatives to be allocated to preexisting political or geographic units, while *districting* refers to how lines are drawn on a map within those units to demarcate the geographic boundaries of individual constituencies. *Malapportionment* refers to differences in the ratio of the number of voters/electors to the number of representatives across different constituencies. *Gerrymandering* refers to the drawing of districting lines for purposes of political (e.g., partisan or ideological or ethnic) advantage/disadvantage. Apportionment and districting practices are reviewed and key issues identified. While there is a particular focus on data from the United States, the general approach is a comparative one.

Most contemporary students of democratic theory take for granted that the basis of political representation will be geographic. There are two key components of any geographic system of representation: apportionment and districting. While the two terms are often used synonymously, formally, *apportionment* refers to the determination of the number of representatives to be allocated to preexisting political or geographic units, while *districting* refers to how lines are drawn on a map within those units to demarcate the geographic boundaries of individual constituencies. *Malapportionment* refers to differences in the ratio of the number of voters/electors to the number of representatives across different constituencies. *Gerrymandering* refers to the drawing of districting lines for purposes of political (e.g., partisan or ideological or ethnic) advantage/disadvantage.

Use of geographical districting leaves open many key questions: How many and how large are the districts to be? Will seats be allocated to whole political units, such as provinces or towns, or will district lines be permitted to cut across existing political subunit boundaries? Will district lines be required to satisfy standards of compactness or contiguity? To what extent will apportionment and districting lines be based (entirely or almost entirely) on total population? Or on population of (eligible) voters?

The United States has been a leader in defining standards of apportionment and districting to implement the principle of popular sovereignty. The U.S. House of Representatives was intended by its founders to be the representative chamber of a bicameral legislature and its apportionment rules were set up to require a purely population-based allocation of House districts to the states, with changes in seat allocations made after each decennial census. Indeed, the various apportionment methods that have been used for the House over the past several centuries are mathematically identical to proportional representation methods such as D'Hondt and Ste. Laguë (Balinski and Young, 1982; also *see* Electoral Systems). These methods differ in how they handle the problem of rounding.

In Baker vs Carr, 369 U.S. 186 (1962), the U.S. Supreme Court held that failure to redraw district lines when new census data were available was unconstitutional and that courts could fashion appropriate remedies. In subsequent landmark districting decisions, such as Reynolds vs Sims, 377 U.S. 533 (1964), the U.S. Supreme Court went much further, proclaiming *one person, one vote* as the only appropriate standard for both districting and apportionment. While one person, one vote notions of representation have had a profound influence throughout the world, by and large, the United States remains extreme among nations in its insistence on strict adherence to one person, one vote standards. For state legislative and local redistricting plans, where the one person, one vote standard is derived primarily from the equal protection clause of the Fourteenth Amendment, Supreme Court cases in the United States have established a 10% total deviation as prima facie evidence of constitutionality, though evidence that districting choices lack a rational justification for deviations from ideal can lead to a plan that is under the 10% total deviation being struck down. (*Total deviation* is the sum of the absolute values of the differences between actual district size and ideal district size of the largest district and the smallest districts, normalized by dividing through by ideal district size.) For Congressional districting, where standards are based directly on the supposed meaning of language in Article I of the Constitution, the Supreme Court has held that districts must be as close to zero deviation as is practicable. For example, in Karcher vs Daggett, 462 U.S. 725 (1983), a Congressional plan with a total deviation of only 0.698% was invalidated. In reaction to this ruling, in some 1990s Congressional plans, districts were drawn that were equal in population to within a handful of persons. In contrast, in other countries, especially those using plurality elections, no such strict population requirements exist. Many countries require (or even only just suggest) that differences should be no greater than ±25 or ±50% of ideal (Butler and Cain, 1992).

However, the notion that near-perfect equality of political representation has been achieved in the United States is misleading. The grossly malapportioned U.S. Senate tends to be omitted from international comparisons despite the fact that it is a coequal chamber. The U.S. House requires that each state has at least one representative – a rule that usually gives representation to several small states who would not otherwise be entitled to seats. Also, since states are the units, 'rounding rules' create variation in average House district population across states. For example, while the average size of a Congressional district based on the 2010 Census apportionment

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93008-3

population was 710 767, the largest House district in the 2010 apportionment was the single district in Montana, with 994 416 people, nearly two times the size of the smallest House district, the single seat in Rhode Island, with 527 624 people. Thus, the total deviation in the entire House of Representatives came to 66% (283 649 in Montana plus 118 465 in Rhode Island). The population discrepancies have been comparable in recent apportionments and even greater in earlier apportionments.

Moreover, even districts that are equal in population need not be equal in terms of (eligible) voters, much less in terms of actual voters. Perhaps most importantly, unless we somehow regard voters as completely interchangeable units, neither population nor voter equality across constituencies, however perfect, guarantees equality of effective representation of the disparate groups and interests within a society. The degree and geographic locus of malapportionment and differential turnout across groups interact with how a group's voting strength is distributed across districts to affect the translation of a group's voting strength into actual electoral impact (Grofman et al., 1997). Indeed, malapportionment is sometimes referred to as a form of *silent gerrymander*, since malapportionment can easily translate into the political disadvantage of groups whose influence has been diminished because their members are disproportionally concentrated in constituencies whose voters have been underrepresented relative to their numbers. Even without conscious gerrymandering, the way in which districting lines are drawn will necessarily have an impact on the representation of different parties or groups (Dixon, 1968).

The term gerrymandering comes from wordplay on the last name of Elbridge Gerry, Governor of Massachusetts. In 1812, Gerry signed into law a districting plan for the Massachusetts Senate, allegedly designed to maximize the electoral successes of Republican-Democrat candidates and minimize the electoral successes of Federalist candidates, which included some rather strangely shaped districts. In a map in the Boston Gazette of 26 March 1812, the strangest of these districts was shown as a salamander, given tongue and teeth (**Figure 1**). Perhaps, the most pernicious aspect of this figure is that it has led to a potentially misleading association of gerrymanders with oddly shaped districts. The defining aspect of a gerrymander is the political consequences it entails, not its shape. Political disadvantage can come about even when districts look like squares or hexagons (Grofman, 1990). In fact, however, the 1812 Senate plan did achieve partisan advantage for the Republican-Democrats; in the next election they won 29 of 40 seats, even though they received less than half of the votes (Hardy, 1990).

Gerrymanders can be classified as partisan, bipartisan (often called 'incumbent gerrymanders'), racial, and personal, depending on who can be expected to be harmed or helped. In the United States, for example, the debate about gerrymandering has been fought largely over racial rather than partisan issues, e.g., over the extent to which plans should seek to place members of historically disadvantaged groups such as African-Americans into districts where they comprise the majority of the population, even if doing so meant drawing districts that were irregular in appearance or cut across municipal and other political unit boundaries (Grofman, 1998).

Figure 1 The infamous original gerrymander (as artistically rendered).

There are two basic techniques of gerrymandering: (1) 'packing' members of the group that is to be disfavored into districts that are won by very large majorities, thus 'wasting' many of that group's votes and (2) 'cracking' the voting strength of members of the group by dispersing the group's population across a number of districts in such a fashion that the group's preferred candidates will command a majority of the votes in as few districts as possible. In addition, if elections are held under plurality, a group's voting strength may be submerged in multimember districts that use bloc voting – a technique sometimes called 'stacking.' A fourth technique has been called 'kidmapping' (Grofman, 1985). Here district lines are moved so that the incumbent previously representing the district now finds his or her home in a different district, perhaps paired with an incumbent of his or her own party.

The terms 'affirmative action gerrymander' and 'benign gerrymander' have been used to denote districting done to advantage members of a historically disadvantaged group. However, it is important to distinguish between plans that are drawn with an aim to create a level-playing field by avoiding unnecessary fragmenting of minority population concentrations, but that otherwise generally take into account the usual districting criteria such as respect for natural geographic boundaries and historical communities of interest, and that seek to specially privilege particular groups by totally disregarding features other than race (or party) in drawing lines.

Because the way in which lines are drawn can be expected to matter, an important issue has to do with who draws the lines. In most democracies, especially those electing under plurality, nonpartisan boundary commissions are responsible for drawing district lines (Butler and Cain, 1992; Handley and Grofman, 2008). In the United States, the preponderant pattern is for a legislature to be responsible for its own redistricting and for each state legislature to be responsible for the

drawing of Congressional district lines for its state. However, in most U.S. legislatures, no plan can be passed without gubernatorial agreement. Because of divided party rule and other factors, states may be unable to reach agreement on plans, thus throwing decision-making into the courts.

One way in which districting practices in the United States are distinct from those in other countries is the extent to which courts play a critical role as arbiter. In recent decades, all but a handful of states have had a legislative or Congressional plan challenged in court, and many plans have been rejected – in the 1960s and 1970s, mostly for reasons having to do with population inequalities across districts; in the 1980s and 1990s, for reasons having to do with racial representation (Grofman, 1998). Indeed, throughout these decades, courts themselves were responsible for drawing some of the legislative or Congressional districting plans that were actually used. Another peculiarity of U.S. districting practices is the role of the U.S. Department of Justice under Sections 2 and 5 of the Voting Rights Act of 1965 as amended in 1982 (Grofman, 1998) in enforcing racial fairness.

From a comparative perspective, we may say that, generally speaking, gerrymandering is more important in plurality elections than in elections under proportional or semiproportional rules. In particular, when there are more than two candidates or political parties competing, districting can have a dramatic impact on outcomes in plurality elections (Taylor et al., 1986). *Ceteris paribus*, for elections under proportional or semiproportional methods, the larger the average *district magnitude* (the number of representatives to be elected from the constituency), the lesser the probable impact of districting choices on outcomes; in contrast, for elections under plurality voting, the greater the average *district magnitude*, the greater is the expected impact on outcomes, since *plurality bloc voting* (the extreme case of which is an *at-large election*) can result in the virtual submergence of the views of those in the minority. However, even under proportional representation, expected outcomes can still be manipulated by districting choices, especially choices as to district magnitude (Mair, 1986).

Electoral Geography

Ron Johnston, University of Bristol, Bristol, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Electoral geography provides a spatial perspective to the study of the organization, conduct, and outcome of elections. Its main focus is on the nature of, and interactions between, three maps. Two refer to the 'inputs' – the geography of support for parties and/or candidates (themselves in many cases a function of the geography of the social groups from which each party draws its main support); and the geography of the constituencies (electoral districts, ridings, etc.) within which votes are cast and counted. The third map shows the outputs, the geography of representation that emerges when the votes are counted and the winners and losers determined. Much research in electoral geography involves the analysis of two types of data. The first is ecological, or aggregate, data; the second is data on individual electors – traditionally the products of voter surveys. Using evermore sophisticated analytical procedures, the two are increasingly combined, enabling the study of individual behavior patterns in their local contexts.

Electoral geography provides a spatial perspective to the study of the organization, conduct, and outcome of elections (Johnston and Pattie, 2012b; discuss its origins and development). No general synthesizing text has appeared since 1979 (Taylor and Johnston, 1979) – apart from one that focuses on British elections only (Johnston and Pattie, 2006) – although a collection of essays has assessed recent developments (Warf and Lieb, 2011); the journal *Political Geography* publishes a number of papers on electoral geography each year.

The main focus of electoral geography is the nature of, and interactions between, three maps (of which, given advances in computer cartography, there is an increasing number of excellent examples – as in Brunn et al., 2011). Two refer to the 'inputs' – the geography of support for parties and/or candidates (themselves in many cases a function of the geography of the social groups from which each party draws its main support); and the geography of the constituencies (electoral districts, ridings, etc.) within which votes are cast. The third map shows the outputs, the geography of representation that emerges when the votes are counted and the winners and losers determined. (Gudgin and Taylor's (1979) book is a classic treatment of these three maps: it was republished, with an extensive introduction, in 2012.) Although most electoral geographers focus on these maps (and others linked to them, as discussed below), there are considerable variations in the relative attention given to each (as Johnston, 2005, illustrates in a US/UK comparison).

Much research in electoral geography involves the analysis of two types of data. The first is ecological, or aggregate, data – the number of votes cast for each candidate in an area, for example; the second is data on individual electors – traditionally the products of voter surveys. Using evermore sophisticated analytical procedures, the two are increasingly combined, enabling the study of individual behavior patterns in their local contexts.

The Geography of Votes

André Siegfried's pioneering essays on *géographie électorale* established cartographic correlations between patterns of party support and French physical, social, and economic landscapes, sophisticatedly linking environment to voting through agrarian systems, land ownership, and rural social stratification and tradition: parties drew their support from different sociospatial milieux (e.g., Siegfried, 1949; Dogan, 1967; Lacoste, 1986, follow in that tradition.)

Siegfried's work showed substantial continuity over time in these patterns of support, as did a further seminal work. Key (1955) demonstrated that continuity in American voting maps reflected stable electoral cleavages, with parties sustained within the same milieux across a sequence of elections. That continuity was occasionally broken, however. An interruption might be only temporary – producing a geography that differed from the 'normal pattern' when substantial numbers of voters deviated from their usual partisan leanings reflecting the particular circumstances of a contest. On other occasions the change was more permanent and a new geography established that was then sustained over a sequence of elections; this reflected realignment in the socioeconomic and sociodemographic support for one or more parties and was represented in the geography of their voting strength. Archer and Taylor (1981) used this framework of normal, deviating, and realigning elections in analyses of the changing electoral mosaics of support for American presidential candidates (Archer and Shelley, 1986).

For the majority of Western European countries, Lipset and Rokkan (1967) identified four electoral cleavages that underpinned support for most of their political parties. Two of those cleavages were initiated following the 'national revolution' and the emergence of nation-states from the seventeenth century on: the first was between the dominant and minority cultures within a state's territory (the core-periphery cleavage); and the second reflected the contest between church and secular interest groups (the church-state cleavage). The other two were products of the 'industrial revolution': the first (the class cleavage) reflected conflicts between employers and workers and the second those between an economy's primary and secondary sectors (the urban–rural cleavage). Of these four, the class cleavage was present in most European countries by the mid-twentieth

century; the relative strength of the others reflected local histories and cultures. The importance of those cleavages has however declined recently – more so in some countries than others. Electoral decisions are less driven by ideological differences – between classes, for example – and more by what are termed 'valence politics' (Clarke et al., 2009): voters, from whatever backgrounds, make their decisions on which party they think can best manage the country on the most important issues of the day, which are usually dominated by the economy and national prosperity.

If cleavages are the main sources of variations in electoral support within a country, then if you know a party's social bases of support the geography of voting for it should be readily 'predicted': if a party gets most of its support from the 'working class,' it should be strongest where members of that class are most numerous. This suggests a uniformity to a country's electoral geography, as illustrated in a classic study of voting in Britain (Butler and Stokes, 1969, 1974). Similarly, if valence politics dominate electoral choice, a party that gets its strongest support from those who are positive about the future economically should attract most votes in areas where optimism prevails.

In both cases, the geography of voting would be relatively straightforward to uncover – if you know a country's economic or social geography, you can readily 'forecast' its electoral geography. But that is rarely completely the case, as Johnston et al. (1998) showed in an analysis of three UK general elections: each political party performed better than expected in some areas and worse in others. In part this reflected the country's uneven geography of prosperity (the 'north–south divide'), but work by Agnew (1987, 1996), building on Cox's (1970) study of the geography of party support in Wales, provided a stronger – inherently geographical – argument for the existence of electoral geographies that are more complex than a simple mapping of national cleavages. Agnew's argument comprised six claims listed below:

1. Class and community affiliations take on different meanings in particular places (as illustrated in Johnston's (1991) essays on British coalfields and the American south).
2. Local communication networks, through which political affiliations are mobilized, may be relatively isolated in particular territories, leading to separate voting patterns.
3. There are continuing tensions between some areas within a state and the national political institutions, engendering local political cultures (as with intrastate secessionist movements).
4. All social cleavages are locally constituted – there is no national class cleavage, for example, only a myriad local ones – which may lead to local variations in electoral support among people with similar backgrounds.
5. Some political parties' histories are rooted in particular places, which become their main areas of electoral support and whose interests they promote in their manifestos.
6. The microgeography of everyday settings – home, neighborhood, work, leisure, etc. – can stimulate local distinctiveness that is reflected in voting patterns.

His own work on Italy (Agnew, 2002; Agnew and Shin, 2008) illustrates these themes.

Local Influences on Voting Decisions

Agnew's sixth claim is the basis for much research that has explored the extent of, and reasons for, variations in voting patterns at local scales that cannot be accounted for by general theories such as those of cleavages and valence politics. Some of the earliest work on this theme derived from Key's (1949) book on elections where party cues are irrelevant. The Democratic Party dominated politics in the American South for nearly a century, where voters' main choices were among the contenders for its nomination. Many candidates performed best in their home areas – creating a 'friends and neighbors effect,' formalized by Reynolds (1969) and Cox (1969).

Cox's (1969) pioneering essay – which in many ways 'launched' the subdiscipline of quantitative electoral geography (Johnston and Pattie, 2012b) – extended the argument underpinning the 'friends and neighbors effects' to the more general concept of a 'neighborhood effect' whereby an area's majority opinion is accentuated if some of their residents who initially favored minority views are won over through a process of 'conversion by conversation.' The thesis that 'people who talk together vote together' was established using survey data (e.g., Huckfeldt and Sprague, 1995; Pattie and Johnston, 2000). Establishing that such conversations underpin observed voting patterns has not been straightforward, however. Many analyses of putative neighborhood effects have relied on aggregate data: their findings are consistent with the argument that a party tends to perform better than expected in areas where its supporters are in the majority, for example, but cannot uncover the processes involved. Research combining survey and aggregate data has gone some way to resolving this problem, however, as in studies using 'bespoke neighborhoods' – small areas separately defined as the immediate milieux to each respondent's home address – to represent the local context (e.g., MacAllister et al., 2001). These have shown that the more that people are involved in their locale, the more open they are likely to be to neighborhood influences (Johnston et al., 2005), while analyses using contextual data at a variety of scales have suggested that variations reflecting neighborhood influences are strongest at more local scales (Jones et al., 2007).

Another set of local influences on voting behavior involves the activities of parties in their search for votes – the local campaign maps. Alongside national election campaigns – which focus through the national media on such issues as policy manifestos, leadership potential, and government performance – are locally organized and focused campaigns. These have three main goals: to build a candidate's profile locally; to identify voters who are likely to support the party/candidate; and then to ensure that those supporters turn out to vote. Early studies of such activities in the United Kingdom used data on the amounts spent on such campaigns as an index of their intensity, and showed that the more that candidates spent (especially challengers rather than incumbents) the better their performance (Johnston, 1987). These findings have been complemented by analyses using other indices of campaign intensity (Denver and Hands, 1997), and confirmed by studies using survey data which show that those contacted by a party (especially those who are not firm in their voting intention: Johnston and Pattie, 2012b) are

more likely to vote for it than those who are not contacted. Since parties tend to concentrate such campaigning not only in the relatively marginal constituencies where either victory or defeat could be the outcome but also in parts of those constituencies where their likely supporters' homes are concentrated (Johnston et al., 2005a), such successful geographically targeted campaigns enhance the processes producing neighborhood effects. US presidential elections are similarly highly focused on the small number of 'swing states' where both candidates have a chance of victory, with the others getting little personal attention from them because the outcome there is taken for granted (Brunn et al., 2011: 29–42).

The Geography of Constituency Definition

The electoral system in most countries involves the use of territorially defined constituencies; the contest for votes is split into a large number of separate areas (Farrell, 2011). Those districts vary greatly in their size depending on the electoral system deployed: in some countries, notably those using single-member constituency systems, the details of their definition can crucially impact on an election outcome because the overall result reflects not just the total number of votes cast but also in how many separate districts a party (or a candidate in a presidential election) wins the largest number of votes.

This issue of where to draw district boundaries has attracted much attention among American electoral geographers, because redistricting there – of Congressional Districts, for example – has traditionally been undertaken by the political party in power in the relevant state, which has sought boundary configurations that promote its electoral interests and penalize its opponents' (Morrill, 1973; Winburn, 2009; Bullock, 2010). Two main 'cartographic abuses' have been identified. The first is malapportionment, whereby constituencies are either created with substantial variations in their population or such variations are allowed to develop with differential population changes (for example, rural to urban and central city to suburban migrations). A party whose electoral strength is in areas where on average constituencies are small will tend to perform better – i.e., win more seats relative to its vote share in the relevant legislature – than one whose strength is in areas where they are larger. Malapportionment was outlawed in the 1960s 'redistricting revolution' and American courts now require that all districts have equal populations. But the second 'cartographic abuse' has been much more difficult to remove. Gerrymandering involves the drawing of constituency boundaries to benefit one party rather than another, and can be practiced even where equality of electorates is the paramount consideration. Much gerrymandering involves the drawing of odd-shaped constituencies, so as to create as many constituencies as possible where the party involved should obtain a majority of the votes (as illustrated by Monmonier, 2002).

Although gerrymandering is a deliberate strategy to promote partisan ends, Gudgin and Taylor (1979) showed that even where the boundaries are drawn by strictly neutral, nonpartisan bodies, nevertheless the equivalent of gerrymandering can be the outcome. They showed – through sophisticated mathematical and statistical reasoning – that, for a given geography of party support, different constituency configurations for an area could result in very different electoral outcomes. Extending their work in the United Kingdom, for example, Johnston and Rossiter (1983) showed that in Sheffield, a city with six constituencies, although the most likely outcome was Labour winning five seats and the Conservatives one, some configurations would give Labour six seats whereas others would see it win only four. Disproportional outcomes – with one party getting a larger share of the seats than of the votes – could thus eventuate even where neither malapportionment nor gerrymandering was practiced.

Further work on this issue in the United Kingdom has identified not only disproportionality in election results as the product of nonpartisan districting but also bias – defined as differential treatment of the parties even when they have the same share of the votes. At the 1997 general election, for example, if – under certain assumptions – Labour and the Conservatives had won an equal share of the votes, Labour could have gained 82 more seats than its opponent (out of 652). Four years later, Labour's advantage in a similar situation could have been 142 seats; in 2005 it could have been 112; and in 2010 – when the Conservatives won 7% points more of the votes – if the two parties had been equal Labour could have won 54 more seats. Johnston et al. (2001; Johnston and Pattie, 2009, 2011a) used a mathematical procedure to decompose this bias, finding that part of it was due to malapportionment, part to an equivalent of unintentional gerrymandering (Labour's votes were more efficiently distributed across the constituencies than were the Conservatives'), part to variations in turnout (there tend to be more abstentions in Labour-held seats), and part to the differential impact of smaller parties. That methodology, which focuses on the two largest parties only (and has been applied to the US Electoral College: Johnston et al., 2005b), has been extended for the analysis of three-party systems (Thrasher et al., 2011; Borisyuk et al., 2010). As a consequence of that bias, the British government changed the rules for redistributions in 2011 to remove any malapportionment effects (Johnston and Pattie, 2012a; Rossiter et al., 2012).

Conclusions

Elections are based on geographies (the maps of party support and the territories within which votes are cast and counted); their conduct involves geographical processes (such as the campaigns conducted by political parties and the informal processes within neighborhoods through which interpersonal influence on how people vote is transmitted); and their outcomes are geographies – a party in government may have much more support in some areas than others, which may well be reflected in its policies, in who gets what, where, in the allocation of public goods and services. These features are present in some form, with a small number of exceptions only, whatever electoral system is used (Johnston and Pattie, 2011b). It is impossible to take the geography out of elections; it is fundamental to the operation of representative democracies.

Abstract

An electoral system is a set of rules governing an election, and many scholars distinguish between three main elements of any system: ballot structure (how and 'for what' a vote is cast); constituency structure (whether, and how, the electorate is divided into territorially defined constitutencies), and the electoral formula (in an assembly election this is the method of translating votes into seats). The main types of electoral formulae are majoritarian, plurality, and proportional. The most common way of classifying electoral systems is to distinguish between proportional (PR) and nonproportional systems. The two main variants of the former are party-list systems and the single transferable vote (STV); the three main variants of the latter are plurality, majoritarian, and (so-called) semiproportional systems. Much debate has focused on the effects of electoral systems, and on 'Duverger's law.' However, most political scientists now argue that the electoral system has only a limited effect on a regime's party system, and hence on its potential for instability. However, the timing of the adoption of PR systems does have an effect, with its early introduction increasing the likelihood of fragmentation in the party system. Moreover, at particular junctures, changes in the electoral system can affect which parties are likely to govern a regime.

An electoral system is a set of rules governing an election. The study of electoral systems has tended to be restricted in a number of respects. First, most research focuses on elections to legislative assemblies and to political executives, even though, of course, many nongovernmental agencies also hold elections as the means of filling various offices. Second, many issues of central concern in the study of electoral systems – such as paradoxes emanating from the application of particular voting rules – are usually studied within the 'theory of voting' branch of rational choice analysis; in some respects, therefore the study of electoral system can be understood as more of an 'applied' social science, while the 'theory of voting' is 'pure' theory.

Elements of Electoral Systems

Following Rae (1971), many scholars distinguish between three main elements of an electoral system: ballot structure, constituency structure, and the electoral formula.

Ballot Structure

There are several different ways in which this can vary, including:

1. The number of votes each voter is permitted. In some systems the voter casts as many votes as there are positions to be filled (e.g., plurality systems with multimember constituencies – as employed in many state legislatures in the USA before the 1960s); in others, voters may cast only one vote irrespective of how many positions are being filled (e.g., the Single Non-Transferable Vote system used in Japan before 1994).
2. The kind of information the voter can reveal in voting. Some systems permit two different kinds of vote to be cast; for example, in the German Additional Member System (AMS) the voter votes for a party candidate in a constituency, as well as for a party for the party list component of the ballot. In many versions of party list systems the voter can reveal both which party they prefer, and which of that party's candidates they prefer. Again, by combining two separate elections, a system may make it possible for voters to reveal extra information about their preferences. For example, in Israel since 1996, voters reveal not merely which party they prefer, but also which party they wish to form the government: the Israeli voter can vote both for a party in the election for the legislature, and for a particular candidate to be prime Minister following that election. Furthermore, in some systems, voters can reveal only their first preference (whether for a party or a candidate), while in others they can provide a rank ordering of the different parties (or candidates); the plurality system used in British parliamentary elections is an example of the former, while the Single Transferable Vote (STV) employed in the Republic of Ireland is an example of the latter. Finally, some electoral systems limit the expression of voter preference to those candidates or parties listed on the ballot, while others allow the 'writing in' of names not on the ballot, or allow the voter to register opposition to all those listed on the ballot by voting for 'none of the listed candidates.'
3. Whether the ballot is open or secret. In the twentieth century it has become the norm for national elections to be contested under a secret ballot, but until the late nineteenth century balloting was a public act. In the USA, parties in the nineteenth century printed their own ballot papers, and in several states the parties used different colors of paper for the ballot so they could tell who had voted for them. Whether the ballot should be secret or not was a major controversy in nineteenth-century political debates, and some of those who advocated an extensive franchise (e.g., John Stuart Mill) still favored an open ballot.

Constituency Structure

There are three main ways in which electoral systems vary in this regard.

a. The election can be conducted on an 'at large' basis, or an election can be held in each of several constituencies. Generally, though with some exceptions, 'at large' elections are held only in smaller territories and when a proportional mechanism is used to allocate seats in an assembly (e.g., The Netherlands). Most national and subnational assembly elections are divided into constituencies.
b. Whether the constituencies are organized on a territorial or some other basis. Although there have been debates about the desirability of a functional, rather than a territorial, basis for representation, most electoral systems use the latter. The odd exceptions include the 'university seats' of the British Parliament that were abolished before the 1950 election. Any territorial subdivision of a polity involves the drawing of boundaries for the constituencies, and how the boundaries are drawn may affect the overall election result. This issue becomes most significant in systems using non-proportional means for allocating seats, but it is still an issue in those using proportional mechanisms.
c. Whether the constituencies are single-member or multi-member. Systems that employ proportional means for allocating seats in an assembly have to use multimember systems, as does the SNTV; other systems do not. Generally, polities using the plurality system for allocating seats have moved towards the exclusive use of single-member constituencies during the twentieth century.

Electoral Formula

This is the way in which votes are connected to the office(s) being contested – in an assembly it is those rules governing how votes are translated into seats. There are three main kinds of formulae:

1. *Majoritarian.* Under these systems, the winning candidate or party must obtain more than 50 percent of the vote. The two most commonly used means for achieving this are the Alternative Vote System (AV), and the double Ballot System (DB). The AV, which is used in Australia, involves voters showing their second, and subsequent, preferences on the ballot form; when no candidate obtains more than 50 percent of the vote, the lowest-placed candidate is eliminated and his/her voters have their second-choice votes counted. This process continues until one candidate attains more than 50 percent of the vote. The DB requires a second election to be held in all constituencies in which no candidate obtains more than 50 percent of the vote; this second contest includes only the two leading candidates from the first election.
2. *Plurality.* Here the candidate(s) with the largest number of votes wins. In relation simply to its electoral formula, the SNTV system is merely a plurality system; however, its very different ballot structure – voters having only one vote each in multimember constituencies – mean that it is a radically different system in its operation.
3. *Proportionality.* This formula attempts to provide a 'fit' between the share of the votes that the candidates or parties obtain, and the share of the seats the parties get in the assembly. There are two main devices for achieving this. One is to use a formula, of which there are a number of variants including d'Hondt and St. Lagüe, that distributes seats to parties on the basis of their share of the vote. The other method is to permit voters to rank-order all candidates, and to redistribute the 'wasted votes' of those candidates who have more votes than they need to get elected; that, broadly speaking, is the basis of STV. Disproportionalities in supposedly proportional systems can occur for three main reasons:

   1. the ways in which electoral boundaries are drawn, if the system is divided into constituencies, thereby giving an advantage to particular parties;
   2. relatively small district magnitude – that is, a small number of seats being contested in each constituency; the fewer the seats in each constituency, the more likely it is that, in aggregate the allocation of seats between parties will diverge from the distribution of total votes. (STV has to be employed in conjunction with relatively small district magnitude; it becomes unwieldy with large district magnitude because of the complexities involved in expressing preferences between a large number of candidates.); and
   3. in party-list systems, through the use of thresholds which require that parties failing to secure a minimum share of the vote will fail to win any seats at all. A threshold of between 2 and 3 percent of the total vote usually reduces the number of parties represented in a legislature quite dramatically, while a threshold of 5 percent (as used in Germany) restricts seriously the number of parties represented.

Classification of Electoral Systems

There are a very large number of possible electoral systems, including many hybrids of the most common types. (An example of such a hybrid is the system used for the French National Assembly, which is a variant of the DB; a second ballot is used, but it is not confined to the two leading candidates from the first ballot. Instead, any candidate with more than 12.5 percent of the vote is permitted, but not required, to take part in the second ballot.) Given this large variety, considerable attention has been given to classifying the main types of system. It is widely agreed that the main distinction is between 'proportional' systems and other types, but there is some disagreement on two matters.

The first is whether the principal division is a bifurcation between 'proportional' and 'non-proportional' systems, or whether a more complex main division is appropriate. The second disagreement concerns how to treat a variety of electoral systems that are sometimes grouped together under the heading 'semiproportional'; these include the SNTV and the Cumulative Vote (CV). (The latter is a system used in Illinois for many years that, in a three-member constituency would give three votes to each voter but would allow the voter to give all three votes to one candidates, give two votes to one candidate and one to another, or to give a single vote to each of three candidates.) Sartori (1994), for example, argues in favour of treating the SNTV as a form of proportional representation (PR), but most scholars do not do so.

The most common classification is to distinguish between those systems that have mechanisms for generating proportional results that are internal to the systems themselves, and which do not depend for their proportionality on the behavior or strategies of voters or candidates, from those that do not.

Proportional Electoral Systems

Within the class of proportional systems there are two main variants – the *party-list* and the *STV* systems, and within the party-list subclass there are four main sub-subclasses:

Party-List

1. *Pure party-list.* In these systems the order of the party's candidates on the list, and hence their likelihood of being elected, is determined exclusively by the party. The voter can vote only for a party and not for a candidate. (Such systems are relatively uncommon, but this system is used in Israel and was used in France in 1945–96, and in a slightly less pure form during the rest of the fourth Republic.)
2. *Voter-choice from party-list.* These systems allow the voter to express a choice between candidates on the party-list, though great variations in the procedures are evident. In some systems it is actually difficult for voters to propel a popular candidate from a low position on the list to a higher one; in other systems it is much easier to do so. These types of system are the most common form of the party-list, having been used in many European countries.
3. *Mixed systems.* The AMS is the principal variant of this type. A proportion of the seats (sometimes one half) are contested in single-member constituencies under plurality voting. The remaining seats are contested using a party-list, and the allocation of seats from the party-list is used so as to correct for any disproportionalities resulting from the elections in the constituencies. This type of system, which is used in Germany and New Zealand, produces election results that are rather similar to those that would occur under other party list systems.
4. *Panachage.* Used in Switzerland, this system permits voter choice between candidates of more than one party. Some experts argue that it is not really a form of party-list system because of this rule, although its operation more closely resembles such systems than any other types.

STV

Unlike party-list systems, STV achieves proportionality in the distribution of seats in a legislature through a mechanism that allocates seats to particular candidates. A party acquires seats through given candidates of theirs receiving sufficient votes to win seats, rather than the parties being allocated votes through a formula that distributes seats directly to the parties.

Nonproportional Electoral Systems

Among the nonproportional systems, there are three main subclasses:

1. *Plurality.* The first-past-the-post system has been used in many Anglo-Saxon democracies, and it is still the system used in Canada, and most of the USA, as well as for elections to the UK Parliament.
2. *Majoritarian.* The most common variants of systems requiring the winning candidate (or party) to win more than 50 percent of the vote are the AV and DB. Outside national elections, there are some majoritarian systems that require the winning candidate to receive more than 50 percent of the vote – one example being the Democratic National Convention which, until the 1930s, required that the nominee for the presidency receive two-thirds of the delegates' votes. Since such systems can produce many rounds of balloting and still fail to produce a result, they are wholly unsuitable for elections at which electors cannot interact personally with each other in an effort to achieve a definite result.
3. *Semi-proportional.* This is a subclass containing several rather different kinds of system, including the CV, SNTV and the Limited Vote (LV). The last is rather similar to the SNTV in that there are multimember constituencies, but, whereas in SNTV voters have only one vote, under LV they have more than one vote, but fewer votes than there are seats being contested. It is employed for some seats in the Spanish Senate, and was used in a few urban constituencies in Britain between 1867 and 1883. Semiproportional systems acquire their (rather misleading) name from the fact that they tend to generate greater representation for smaller parties than does the plurality system. However, the objection to classifying them as a form of proportional system is not that they tend to produce disproportional results – though in fact they do tend to do so – but rather that how proportional they are depends on the particular behaviour of voters and parties. In some situations they may not be proportional at all. By contrast, proportional systems are designed to generate a degree of proportionality.

Consequences of Electoral Systems

Public and academic interest in electoral systems tends to be much greater when the franchise is being extended (as in Britain in the 1860s), or new legislative assemblies are introduced (Britain in the 1990s) when democratic regimes have collapsed or are unstable (Europe from the 1920 to the 1950s), and when regimes are democratizing (Eastern Europe in the 1990s), or redemocratizing (Latin America in the 1980s and 1990s). One of the main focal points of attention is the likely consequences that one form of electoral system will have compared with others.

In the 1950s, and in light of the experience of collapsed democracies in the interwar years and with the potentially unstable regimes in postwar France and Italy, Duverger (1959) propounded an argument that has come to be known as Duverger's Law: 'the simple-majority single ballot system favours the two-party system'. He also argued that PR tended to be associated with multipartism. His argument was often linked to the widely held view in Britain and the USA at that time that PR was responsible for unstable governments with multiparty systems, of the kind found in the fourth Republic, whereas plurality

systems were a recipe for stable two-party democratic government.

Since Duverger's Law was first propounded it has had its critics, and at the time of writing many political scientists would point to its limitations. It does not apply when there are strong regional cleavages, for example; they also reject the popular view that PR was causally responsible for unstable government. That view does not fit well with the evidence: most European countries since 1945 have used some form of PR, and most have had multiparty systems and coalition governments, yet most have not had unstable regimes. Although there are some exceptions, notably Sartori (1994), many political scientists now argue that the electoral system has only a limited effect on a regime's party system, and hence on its potential for instability. Increases in the number of parties in a system, for instance, tend not to follow the introduction of PR, but rather tend to precede it; moreover, the timing of the introduction of PR is significant in relation to whether party fragmentation will occur. An early switch to PR following democratization does tend to produce fragmentation – because the larger parties have had limited opportunities to develop loyal electorates. A switch much later does not lead to fragmentation, because the established parties now have loyal electorates who are not likely to defect to new or small parties.

Nevertheless, the precise form of electoral system used can have an impact on election results: changing the rules does change the political game. For example, the switch from plurality voting to AV in British Columbia in the early 1950s probably did prevent the socialist CCF party from gaining power in that decade. Similarly, the switch to PR from DB for the 1986 Assembly elections in France helped to minimize the Socialists' losses and to establish the National Front as a credible party that could win seats in the Assembly. Electoral systems cannot transform the social bases of electoral politics, but they can make it more likely that some parties will win office, or share power in government, and make it less likely that others will do so. For that reason, politicians are tempted sometimes to change them. For the most part, though, they are not changed frequently – partly because those in office are the people who usually benefit from the working of the existing system, and partly because the full consequences will be unknown, and hence might actually run counter to the interests of those seeking change.

Abstract

Electroencephalography is the discipline of analyzing and interpreting electrical waveforms recorded from the scalp or cortex, usually in a clinical context. Physiologic, technical, and interpretive principles must be mastered for meaningful results. Diagnostic applications include epilepsy, disturbances of consciousness, brain death, dementia, cerebrovascular or structural brain disease, and to a limited extent, psychiatric disorders. Long-term monitoring indications include epilepsy, coma, and certain surgical procedures. Computer processing techniques may compliment expert visual waveform analysis in selected brain diseases and efforts to apply them to psychiatric or cognitive assessments show promise but presently remain investigational.

Introduction

An electroencephalogram (EEG) is a recording of fluctuating electrical waveforms at the scalp. An electrocorticogram (ECoG) is a similar recording made directly from the cortex. Electroencephalography is the discipline of analyzing and interpreting these waveforms, usually in a clinical context. This article describes some basic principles and applications.

Physiologic Principles

A synapse on a cerebral neuron produces an excitatory (depolarizing) or inhibitory (hyperpolarizing) postsynaptic potential that generates electric current inside and outside the cell. By integrating many sequential or simultaneous synaptic inputs, each neuron exhibits continuously changing postsynaptic potentials. The resulting extracellular currents volume conduct through tissue, but their strength declines with the square of distance. Thus, single neuron electrical activity recordable with a microelectrode in or very near the cell is too weak to register farther away. Fortunately, synchronous extracellular currents of many neurons can spatiotemporally summate to generate aggregate potentials strong enough to record at the cortical surface or even the scalp (Buzsaki et al., 2002; Speckmann and Elger, 2005).

The uniform radial geometry of cortical pyramidal neurons enables spatiotemporal summation, while the potentials of other more randomly oriented cortical or subcortical cells tend to cancel out (Buzsaki et al., 2002; Speckmann and Elger, 2005). Thus, EEG selectively records synchronous electrical activities of pyramidal neuron populations. However, oscillating subcortical–cortical synaptic circuits modulate pyramidal neurons, thereby contributing to rhythmic waveforms that may indirectly reveal subcortical influences (Buzsaki et al., 2002; Speckmann and Elger, 2005).

Synchronous potentials of many pyramidal neurons are needed to generate scalp signals. For example, registering a spike at the scalp requires a synchronous neuronal discharge under a cortical surface area of about 5–6 cm^2 (Ebersol, 2002a). Cortical potentials diffuse as they propagate through intervening tissues, especially the skull, thereby spreading out over large scalp areas. Each of the resulting scalp fields has a peak surrounded by declining voltage, like a hill (Ebersol, 2002a,b; Connolly and Sharbrough, 2002). Many fields are dipolar, having negative and positive poles with voltage gradients between and around them, like a hill and valley (Ebersol, 2002a,b). Depending on the source, the poles may be nearby, widely separated or on opposite sides of the head, and they may have similar or different amplitude and gradients. Focal superficial cortical sources generate relatively localized peaks and steep gradients, while deep or diffuse cortical sources generate broad gradually sloping fields. Localizing an EEG potential involves analyzing its field as sampled by all scalp electrodes in order to estimate the generating cortical region (Ebersol, 2002a,b). The inevitable overlap of fields from different cortical regions can complicate localization.

Because ECoG involves less spatiotemporal summation and diffusion, one obtains more focal recordings: a high-voltage discharge at one electrode may be absent a centimeter away. Localization therefore considers each electrode separately and the activity of unrecorded cortex is unknown. The difference between EEG and ECoG can be likened to viewing a forest vs. viewing a sample of individual trees.

Some Technical Principles

Modern EEGs are digital (Krauss and Webber, 2005). The instruments have multiple solid-state amplifiers, or channels. The analog output of each amplifier is digitally sampled and stored to disk as a time series of discrete signed integer values in a binary file. To accurately record high frequencies, the analog to digital (AD) conversion sampling rate must exceed twice the highest frequency of interest. For standard clinical EEG the highest frequency is 70 Hz and 200–256 Hz sampling is sufficient. When higher frequencies are desired, the sampling rate must be increased proportionally. The vertical resolution depends on the number of AD converter bits, typically 12 ($2^{12} = 4096$ points), 16 ($2^{16} = 65\ 536$ points), or 24 ($2^{24} = 16\ 777\ 216$ points).

The size of a digital recording varies with its duration, channel number, AD bits and sampling rate. For example, a 16-channel 20-min EEG with 12-bit 200 Hz sampling may be only a few

megabytes, whereas a 256-channel 24-h recording with 24-bit 4000 Hz sampling may be several gigabytes. Patient digital video further increases size. The system's processing and storage capacity has to match its intended purpose.

Each differential amplifier measures and amplifies the voltage difference between two inputs (I_1 and I_2). This is done by electronically subtracting I_2 voltage relative to ground (G) from I_1 voltage relative to ground, so that $(I_1–G) – (I_2–G) = I_1–I_2$. By convention, the deflection is up in the event that I_1 is more negative than I_2 or I_2 is more positive than I_1, and down in the event that I_1 is more positive than I_2 or I_2 is more negative than I_1. Ideally there is no deflection when the difference is zero, but in reality a small degree of common-mode gain does occur with voltages common to both inputs. The common-mode rejection ratio (CMRR) is the ratio between differential and common-mode gain. Modern EEG amplifiers have very high CMRR typically exceeding 110 dB. Other important specifications include high input impedance and low amplifier noise.

Recordings are usually made from each electrode (E_1, E_2, …, E_n) as I_1 to a recording reference (R) as I_2. Thus, $E_1–R$, $E_2–R$, …, $E_n–R$ are recorded to disk and to see what $E_1–E_2$ was, one simply computes $(E_1–R) – (E_2–R) = E_1–E_2$. In this way, any desired derivations can be reconstructed from the stored raw data during review. Display sensitivity, montage and digital filter settings are also freely adjustable. These benefits are a major advance over older unmodifiable analog recordings written to paper.

Another digital benefit is the ability to process the EEG with computer algorithms (Lopes da Silva, 2005). For example, interpolation estimates what scalp potentials might have been in-between the recording sites at any one moment. Mapping the results with a color gradient or contour line plot on a cartoon of the head may compliment visual analysis or help to communicate findings. However, one must be aware that the interpolated values are estimates based on assumptions and subject to error. Recording from more electrodes to increase spatial sampling of real data improves accuracy (Gevins, 1998). Although EEG maps are graphic, they are not anatomical brain images.

Source dipole localization attempts to estimate the location, direction, and strength of a cortical dipole source that could explain an interpolated scalp field (Ebersol, 2002b). This is done with mathematical head models that vary from simple spherical approximations to complex individualized models based on the patient's neuroimaging. Results vary with the number of electrodes, model sophistication, and the algorithm used.

Fast Fourier transformation converts selected EEG segments into the frequency domain (Lopes da Silva, 2005). The results quantify signal power at every frequency for each channel and are often divided into bands, typically delta (<4 Hz), theta (4 to <8 Hz), alpha (8–13 Hz), and beta (>13 Hz). Beta may be subdivided into beta (13–30 Hz) and gamma (>30 Hz), although distinguishing gamma waves from cranial muscle potentials is problematic because their frequencies overlap. Quantification can compliment expert waveform interpretation and makes statistical comparisons to normative data possible, although this type of analysis is mostly a research tool (Nuwer, 1997). Again, interpolated frequency content maps can aid interpretation or communication. Expert selection of appropriate EEG segments is critical to avoid misleading results (Nuwer, 1997).

Spike and seizure detection algorithms attempt to automatically flag epileptic events, but are imperfect and require expert review and revision (Gotman, 2002). Autocorrelation, cross-correlation and chaos theory calculations are some other processing techniques having various and so far mostly research uses (Lopes da Silva, 2005).

Recording Principles

Personnel

Properly recording an EEG requires training and experience. Technologists undergo a 2-year program followed by a 1-year practicum and become qualified after board certification; some jurisdictions also stipulate continuing medical education and periodic recertification. These requirements underscore the principle that technologist skill is critical for the quality and validity of EEG results.

Patient Preparation

The patient is greeted and brought into a private, relaxed recording room. The technologist explains the procedure and summarizes the patient's medical data taken from the referral, chart, and interview. This is important for anticipating special recording procedures and for enhancing subsequent interpretation. Some patients need to be partially sleep deprived the night before. Some may require sedation that must follow hospital policies and procedures. Very ill patients may need nurse attendance and critically ill patients must have a portable bedside EEG.

Head Measurement

The international 10–20 system for electrode placement defines 21 standard scalp coordinates derived from four anatomical landmarks: the nasion, the inion, and the two preauricular points (**Figure 1**; Tyner et al., 1983). The technologist locates and marks each 10–20 coordinate using a millimeter tape measure and skin pencil. Accuracy takes practiced skill and is critical for valid results and comparisons across time or between patients. Electro-caps consisting of an elastic cap with embedded electrodes approximating 10–20 sites are considered too inaccurate for routine clinical use. An international 10–10 system defines additional coordinates midway between and below 10–20 sites and may be applied to increase spatial sampling. Some laboratories routinely include one of variously defined sites below F_8 and F_7, or a row of inferior temporal sites. The recording reference is typically between C_z and P_z, and the ground is usually on the forehead; both should be on the head, but their exact locations are less critical.

Electrode Application

Standard precautions (hand washing, gloves, personal protective barriers) apply to all patients. Additional transmission-based precautions apply to patients with active infectious disease. Scalp EEGs are normally recorded with reusable 0.5- to 1-cm

Figure 1 The international 10–20 system. Fp, frontopolar; F, frontal; C, Central; T, temporal; P, parietal; O, occipital; A, auricular; odd numbers are left, even numbers are right and z (zero) is the sagittal midline. Ten or 20% of the distance between the nasion and inion, between the two preauricular points (PP), and along each hemi-circumference determines most coordinates. Half the distance along the parasaggital planes (Fp_2 to O_2 through C_4 and Fp_1 to O_1 through C_3), the frontal plane (F_8 to F_7 through F_Z) and the parietal plane (T_6 to T_5 through P_Z) completes F_Z, C_4, C_3 and P_Z coordinates. F_4 is at the intersection of lines drawn midway between Fp_2 and C_4 and between F_8 and F_Z, thus making F_8–F_4 and F_4–F_Z distances equal and also making Fp_2–F_4 and F_4–C_4 distances equal; the same approach defines F_3, P_4 and P_3. A_2 and A_1 are on the earlobes or adjacent mastoids.

diameter metallic cup electrodes that provide excellent recording and safety; needle electrodes are not used because of infection risks. The hair and scalp should be clean and dry. The skin at each measured site must be rubbed with a mildly abrasive gel using a cotton-tipped applicator in order to reduce epidermal impedance to below 5 kΩ.

Each electrode is pressed onto to the prepared skin with a conductive paste to adequately secure it in place for a routine EEG. In the case of long-term or intraoperative EEGs needing firm attachment, electrodes filled with conductive paste or gel are glued to the skin with collodion that is subsequently dissolved with acetone for removal.

Lead wires are bundled or braided together to reduce extraneous electromagnetic interference. Tight braiding is crucial in the operating room and other electrically noisy environments.

Calibration

Because amplifiers exhibit performance variations and degrade or fail over time, the instrument must be internally calibrated before making patient connections. This ensures equal time axis, filter response and output amplitude for a known input voltage across all amplifiers. Additional biologic calibration optionally done after making patient connections ensures that each amplifier produces an identical output waveform in response to a single patient input.

Recording

A routine EEG of a conscious patient primarily assesses the relaxed awake state with the patient supine on a stretcher. Maneuvers to alert or relax patients may be needed. Segments with eyes open and closed assess occipital rhythms generated by visual cortex. Similarly, voluntary hand movements test central rhythms generated by sensorimotor cortex. Segments of hyperventilation, photic stimulation at several flash frequencies and of sleep if time permits are routine activation procedures mainly intended to bring out epileptiform abnormalities. Additional activation procedures such as reading, watching television, playing a video game, standing, listening to music, etc. may be indicated by the patient's history. The technologist adapts procedures to the history and adjusts technique according to observed waveforms and patient behavior. This includes testing responsiveness, memory, language and motor function during a suspected seizure. Frequent annotations of eye opening and closing, swallowing, movements, state and behavior are important. Patient video recording is a useful adjunct.

The minimum standard recording time is 20 min; longer recordings are encouraged. The standard bandwidth is 0.3–70 Hz with the 50 or 60 Hz notch filter off unless absolutely necessary. The minimum standard number of channels is 16, but more are encouraged, including additional EEG channels as well as ECG, eye movement and other adjunctive monitors as indicated. Display gain is adjusted to utilize dynamic range while avoiding trace overlap or clipping.

A sleep EEG may be indicated for suspected epilepsy after a negative routine EEG, or occasionally for excessively agitated patients impossible to record while awake. Partial sleep deprivation promotes sleepiness and sedation may also be needed. These recordings primarily attempt to record as much sleep as possible including slow wave sleep. Sometimes an awake and sleep EEG are both done during the same visit.

EEGs of stuporous or comatose patients are adapted to the level of consciousness and include tests of reactivity to auditory, visual, and sensory stimulation. There are special technical requirements for ancillary EEG testing of clinically diagnosed brain death (Chatrian and Turella, 2002). These include a minimum 30-min recording time, high display gain, long interelectrode distance montages, recording system integrity confirmation, and excluding hypothermia or sedation.

Long-term video-EEG or ECoG monitoring lasting days or weeks may be done for the investigation of epilepsy. The technologist trims these recordings through visual scanning assisted by computer-flagged patient push-button events and imperfect software detection of possible epileptic patterns. The trimmed segments are presented to the electroencephalographer for interpretation.

Monitoring is also done in the intensive care unit or operating room in an effort to detect adverse changes that may prompt intervention to prevent brain injury or titrate medical therapy of status epilepticus. These recordings need real-time interpretation by sufficiently trained personnel. Intraoperative ECoG may be used to tailor cortical resections for intractable epilepsy; the electroencephalographer must be in the operating room because the decisions are irrevocable.

After Recording

After recording, the technologist removes scalp electrodes and wipes off paste or gel while inspecting for rare skin reactions or abrasions; residual materials wash away with normal shampooing. The electrodes, leads, and exposed instrument surfaces are cleaned and disinfected for subsequent use. An exception occurs after recording a patient with suspected Creutzfeldt–Jakob disease, when the electrodes are sterilized or destroyed. Direct cortical and depth electrodes are always destroyed after use. The technologist reviews the recording and ensures everything is in order for clinical interpretation.

Interpretative Principles

Personnel

Properly interpreting an EEG requires extensive training and experience. Prerequisites for clinical EEG fellowship training are being a physician with fellowship training and board certification or eligibility in neurology or another relevant specialty. Fellows study EEG full-time for at least six to 12 months and often longer. In some countries, EEG is part of a comprehensive clinical neurophysiology residency after medical internship. Full qualification requires board certification; some jurisdictions also stipulate continuing medical education and periodic recertification. These requirements stress the principle that broad in-depth expertise is essential for clinically meaningful interpretation.

Artifact Discrimination

Scalp EEGs are highly amplified to register signals in the range of tens of microvolts. Consequently, many potentials are not actually from the brain, but rather from other biologic or nonbiologic sources and these ever-present artifacts must be consistently excluded from interpretation. In fact, there are no truly artifact-free segments and it can be helpful to think of the EEG as an 'electroscalpogram.' In extreme cases, brain activity can be so obscured that no interpretation is possible. After proper training and experience it becomes second nature to recognize artifacts, but some can still be challenging. Inexpert readers can easily mistake artifacts for brain waves.

Biologic artifacts include electromyographic signals from scalp, extraocular, pharyngeal and neck muscles, blinking and other eye movements, tongue movements, ECG, pulse and balistocardiographic artifact, sweat artifact, and others. Nonbiologic artifacts include 50 or 60 Hz and other extraneous electromagnetic interference including cell phones, electrode artifacts consisting of transient 'pops' or more sustained rhythmic potentials, movement artifacts, electrostatic discharges, dissimilar metal artifact from dental fillings, amplifier noise, and others.

Sleep EEGs contain fewer artifacts because of patient stillness and cranial muscle relaxation, but are not artifact free. ECoG contains relatively few artifacts because of lower amplification to register signals in the range of hundreds of microvolts. Nevertheless, artifacts still arise.

Processed EEG methods accentuate the problem because computer algorithms do not distinguish artifacts from brain signals. Consequently, meaningful results require expert selection of relatively clean EEG segments to process, while keeping in mind that there is always some residual artifact (Nuwer, 1997).

Normal and Benign Variant Patterns

The electroencephalographer must master the full range of normal and benign variant EEG patterns at all ages and states (Kellaway, 2002; Niedermeyer, 2005a,b; Westmoreland, 2002). Normal 'background' consists of several overlapping, waxing-and-waning rhythms, and transient waveforms generated by different cortical regions. Momentarily higher amplitude or isolated background waveform components may suggest abnormality, but morphologically fit in with ongoing rhythms in other segments, thereby being normal. Normal intermittent transient waveforms may simulate abnormality either alone or in random combination with other background components. All these normal features exhibit highly variable amplitude and commonly have sharp contours.

Criteria based on frequency, distribution, morphology, polarity, state, reactivity, amplitude, and symmetry define normal patterns and their variations. For example, the occipital alpha rhythm is an 8–13 Hz posterior sinusoidal, notched, or sharply contoured rhythm of variable regulation, persistence, and amplitude that may differ by up to 50% between the two sides of the head. It is present in relaxed wakefulness with eyes closed and 'reacts' (attenuates or desynchronizes) bilaterally to eye opening or mental effort. It may persist into early drowsiness, but disappears in sleep. The fast alpha and slow alpha variants consist of occipital rhythms having approximately twice or half the dominant alpha frequency and showing identical reactivity. Another

normal variation consists of persistently low voltage (<20 μV) or even absent occipital alpha rhythm.

Similarly, the central mu rhythm is an alpha-frequency rhythm of variable persistence and amplitude that may differ by up to 100% between sides and is present in a minority of normal subjects. It has an arciform morphology with negative sharp peak and rounded positive trough. It appears in relaxed motionless wakefulness with eyes open or closed, attenuates with movement planning or execution or with somatosensory stimuli and may persist into early drowsiness but disappears in sleep.

Normal beta (>13 Hz) activity is generalized but frontal dominant, sinusoidal, sharply contoured or bursting with variable <50-μV amplitude that may differ by up to 35% between sides. It is present in wakefulness, may persist or increase in drowsiness, subsides in deep sleep and shows no specific reactivity.

Some other criteria-defined normal patterns include lambda waves, certain slow activities such as posterior slow waves of youth, hyperventilation, and photic stimulation responses, drowsy patterns and vertex waves, sleep spindles, k-complexes, and positive occipital sharp transients of sleep.

Normal background evolves from infancy to old age (Niedermeyer, 2005b). Infants' EEGs are dominated by delta and theta activity that gradually declines through childhood to adult appearance dominated by alpha and beta frequencies. The occipital dominant rhythm first appears around 3 months and is at least 5 Hz by 1 year, 6 Hz by 4 years, 7 Hz by 5 years, and 8 Hz at 8 years of age or older (Lüders and Noachtar, 2000). Sleep spindles are typically asynchronous and sharply contoured between 3 and 12 months of age. Posterior slow waves of youth are prominent in children and teenagers but occasionally persist into the 20s or rarely even 30s. A few intermittent temporal and generalized slow activities may arise during normal senescence.

Furthermore, several infrequent benign variant patterns resembling epileptiform discharges (small sharp spikes, wicket waves, 14 and 6 Hz positive bursts, and 6 Hz 'phantom' spike-and-wave), or seizure-like patterns (rhythmic mid-temporal theta, subclinical rhythmic electrographic discharges of adults, midline theta, and frontal arousal rhythm) must be recognized by their criteria and excluded from clinical diagnosis (Westmoreland, 2002).

Abnormal EEG Classification

Structured classification of EEG abnormalities is recommended to encourage precision, enhance communication, facilitate research, provide a framework for trainees, and make EEG an objective criteria-based discipline. There are various systems, mostly unpublished and institution-specific. The author recommends the published classification of Lüders and Noachtar (2000). It provides well-selected abnormal categories (**Table 1**) defined by criteria along with localization and grading rules, as well as established clinical correlations and excellent illustrations. Fully describing all these abnormalities is beyond the scope of this article. Another published system that may gain prominence is 'SCORE' (standardized computer-based organized reporting of EEG) (Beniczky et al., 2013).

Approach to Clinical Interpretation

The EEG is first read without knowing the patient's clinical history to prevent bias and ensure independent assessment. The electroencephalographer classifies the findings based on criteria. Then the patient's clinical information is reviewed. Finally, the classification and clinical data are merged to synthesize an interpretation setting forth the likely meaning of the EEG classification for that patient. Adherence to this approach progressively hones skill though clinical practice.

Care must be taken to avoid over interpretation that can lead to misdiagnosis, especially of epilepsy. Spikes and sharp waves are the interictal epileptiform abnormalities that correlate with epilepsy (Niedermeyer, 2005c; Lüders and Noachtar, 2000; Zifkin and Cracco, 2002). They are sharp, brief (20–200 ms) cerebral transients that are unequivocally distinct from background and do not conform to criteria for any other normal, benign variant or abnormal waveforms. Thus, the reader must have a full command of EEG to reliably distinguish epileptiform abnormalities. Inexpert readers can easily over-report or miss them. In fact, trainees develop through three

predictable stages. In the first stage they perceive almost anything sharp as an epileptiform abnormality. In the second stage they perceive almost nothing sharp as abnormal because there are so many normal sharp waveforms. In the third stage they find objective balance and exhibit progressively reliable discrimination. The same learning process applies to other EEG abnormalities.

Montages

A montage is a combination of channel organization and analysis technique intended to facilitate localization and comparisons between homologous regions or channels and across the coronal planes (Connolly and Sharbrough, 2002). The problem of presenting time-varying signals from the three-dimensional surface of the head on a two-dimensional display is similar to the cartographic problem of mapping the globe on a sheet of paper: spatial distortion is inevitable, but can be minimized. To this end, montages should be anatomically logical, organized front to back (longitudinal) or side-to-side (transverse) and consistent with the laboratory's chosen left over right or right over left convention.

Longitudinal channels are usually organized into midline, parasaggital and temporal groups. Homologous groups of the two sides may be paired together in the display to aid regional symmetry assessment, or unpaired to minimize spatial distortion and enhance the display of peri-sagittal features or hemispheric asymmetry. Alternating longitudinal montages display sequential channel pairs to facilitate homologous channel comparison, but increase spatial distortion. Transverse montages facilitate coronal comparisons with minimal spatial distortion and are usually organized into frontopolar, frontal, central, parietal, and occipital groups. Thus, there are four basic channel arrangements: paired group longitudinal, unpaired group longitudinal, alternating longitudinal, and transverse (**Figure 2**). Cartographers would prefer unpaired group and transverse displays, but there are valid indications for the others.

The three analysis techniques are bipolar, referential and source derivation. Each has strengths and weakness for displaying and localizing various EEG signals. Bipolar technique measures sequential potential differences across electrode chains. Localization considers mainly 'phase reversal' and 'end of chain' effects. Bipolar montages can provide reasonable background feature differentiation, good symmetry

Figure 2 The same EEG segment displayed with four different montages. Av, average; sd, source derivation; $A_{12} = (A_1 + A_2)/2$. Paired group montages facilitate homologous group comparison, unpaired group displays minimize spatial distortion, alternating montages aid homologous channel comparison, and transverse displays enhance coronal comparison. In this example, bipolar technique provides reasonable background differentiation, but blurs together some features, while source derivation better separates background patterns, such occipital (O_2, O_1) alpha and central (C_4, C_3) mu rhythms. Both referential techniques exhibit background rhythm reference contamination causing spurious frontal derivation alpha activity and poor background differentiation. Common average is useful for analyzing focal abnormalities or dipolar scalp fields and linked-ears can enhance broad peri-sagittal fields, such as sleep potentials, generalized epileptiform abnormalities, or fronto-central beta activity as seen in this example.

assessment, and generally display focal features well. However, they distort broad scalp fields and are subject to spurious asymmetry due to uneven electrode placement, as well as in-phase cancellation when two electrodes equally near to a scalp field peak are in the same channel.

Referential technique measures potential difference between each electrode and a reference common to all channels. The reference may be the ipsilateral or linked ears, the recording reference, another strategically chosen electrode, or the common average of all electrodes usually excluding frontopolar and ear leads. The principle is to select the least active reference for the waveform of interest. Localization considers mainly amplitude. Referential montages can display localized and broad scalp fields well and are less subject to spurious asymmetry. However, they are subject to reference contamination when the reference is active for the waveform of interest. The common average reference can aid focal and dipolar scalp field analysis, but is often contaminated by background rhythms and broad fields, so is suboptimal for assessing these features. The linked-ear reference enhances broad perisagittal scalp fields, but can be contaminated by posterior background rhythms or temporal scalp potentials, so is often suboptimal for analyzing these features.

Source derivation technique (Hjorth, 1991) measures potential difference between each electrode and a weighted average of its three or four closest neighboring electrodes or alternatively, all the other electrodes. The weighting coefficients are the squares of the reciprocal distances from the central electrode and normalized to a total value of -1. The sum of the partial products is then added to the central electrode weighted $+1$. The effect is a high-pass spatial filter that tends to 'de-blur' scalp potential fields. Localization considers mainly amplitude. Source derivation facilitates background differentiation, symmetry assessment and focal scalp field analysis. However, it reduces overall amplitude, distorts broad fields and is subject to spurious phase reversals.

Thus, the four display methods and three analysis techniques combine into 12 fundamentally different montage types. Electroencephalographers naturally develop individual preferences, but must be fluent with all montages and able to select one that optimally displays and localizes the waveform of interest.

Applications

Epilepsy

Epilepsy is the main EEG indication. Epileptic neurons exhibit abnormally large and prolonged membrane discharges called paroxysmal depolarizing shifts. When these occur synchronously in a large enough number of epileptic pyramidal neurons, spatiotemporal summation generates an EEG spike or sharp wave discharge (Niedermeyer, 2005c). Thus, epileptiform abnormalities are uniquely relevant to epilepsy and are not disclosed by any other test apart from the related magnetoencephalogram.

Interictal epileptiform abnormalities correlate very highly with epilepsy, but infrequently arise in patients who have not had a clinical seizure and are not always found in epileptics. Thus, their presence can support, but not prove a clinical diagnosis of epilepsy, and their absence cannot rule out epilepsy. Regional epileptiform abnormalities suggest focal epilepsy (Figure 3), while diffuse ones suggest generalized epilepsy that may be primary if background is normal (Figure 4), or symptomatic of an underlying brain disease if background is abnormal. These diagnostic refinements can guide treatment decisions. For example, different anticonvulsant medications may be indicated for generalized or focal seizures, and surgery may be considered for medically intractable focal epilepsy.

Some types of epileptiform abnormality can point to certain syndromes, such as West syndrome, Lennox-Gastaut syndrome, benign Rolandic epilepsy of childhood, juvenile myoclonic epilepsy, absence epilepsy, or temporal lobe epilepsy (Niedermeyer, 2005c). Syndromic diagnoses may further refine treatment and prognosis. For example, Lennox-Gastaut syndrome is characterized by lifelong intractable seizures and mental retardation, juvenile myoclonic epilepsy is usually lifelong but often easily controlled by medication, and benign Rolandic epilepsy of childhood predictably remits after puberty.

Seizures are infrequent during routine EEGs, but are regularly obtained by long-term monitoring, often done with anticonvulsant tapering. The recording of an EEG seizure pattern is diagnostic and can localize the cerebral region of seizure onset, or demonstrate a generalized onset (e.g., Figure 5). The recording of an ECoG seizure pattern with intracranial electrodes can more precisely localize epileptogenic cortex and may be necessary for selected patients considering epilepsy surgery. The absence of a seizure pattern during a clinical attack resembling an epileptic seizure can help to establish an alternative diagnosis, such as convulsive syncope or psychogenic events. Thus, monitoring is important for the evaluation of epilepsy surgery candidates as well as for seizure classification and differentiation between epileptic and nonepileptic attacks.

Some research frontiers in epilepsy include analysis of infra slow and gamma activities (high-frequency oscillations) that might have localizing value, as well as efforts to treat epilepsy with implanted electrodes and microchips attempting to predict seizure onset and then initiate electrical stimulation hoping to abort a seizure.

Disorders of Consciousness

Impaired consciousness is another common EEG indication. Bihemispheric and/or brainstem malfunction is necessary to reduce consciousness. The clinical manifestations range from mild confusion and disorientation to stupor with impaired responsiveness to unresponsive coma; encephalopathy is a generic clinical term applied to these states. The EEG typically shows generalized nonspecific abnormalities, most often consisting of various types and degrees of slow activity roughly correlating to clinical severity (Lüders and Noachtar, 2000; Chatrian and Turella, 2002; Zifkin and Cracco, 2002). When sedative drugs are contributing, there may be intermingled excessive fast activity. With severe encephalopathy there may be triphasic waves, periodic discharges, burst-suppression or background suppression. A monorhythmic unresponsive

Figure 3 Right anterior to mid temporal (F_8, T_4) sharp waves displayed with a paired group longitudinal source derivation (sd) montage. Based on this focal interictal epileptiform abnormality, the patient's clinical diagnosis was revised from generalized epilepsy with tonic-clonic seizures to temporal lobe epilepsy with secondarily generalized seizures.

Figure 4 Generalized polyspikes and spike-and-wave complexes displayed with an unpaired group longitudinal linked-ear (A_{12}) referential montage. The diffuse interictal epileptiform abnormalities arising from normal background supported the patient's clinical diagnosis of primary generalized epilepsy with myoclonic and tonic-clonic seizures.

Figure 5 A generalized 3 Hz spike-and-wave seizure pattern displayed with an unpaired group longitudinal linked-ear (A_{12}) referential montage. The patient was unresponsive with rhythmic eye blinking and amnesia during the 17-s event. The recording is diagnostic of primary generalized absence epilepsy and corrected a mistaken clinical diagnosis of temporal lobe epilepsy.

alpha coma pattern is sometimes seen as an agonal rhythm in hypoxic–ischemic encephalopathy.

Typically the EEG confirms encephalopathy, but does not disclose the etiology or prognosis. However, in certain clinical contexts, severe abnormalities such as burst-suppression or suppression can indicate a grave prognosis and thereby assist clinical management decisions (Chatrian and Turella, 2002). Sometimes the EEG reveals a status pattern leading to a diagnosis of potentially reversible nonconvulsive status epilepticus causing or contributing to the impairment of consciousness. In this case, anticonvulsant treatment might promote recovery. Focal slow activity or asymmetry may suggest other treatable etiologies, such subdural hematoma or focal brain lesion, but these possibilities are better evaluated with neuroimaging. Long-term monitoring may increase detection of potentially treatable conditions or complications and can also guide the titration of medical therapy for status epilepticus. Rarely a surprisingly normal EEG in an unresponsive patient may suggest psychogenic unresponsiveness, catatonia or locked-in syndrome (motor paralysis with preserved awareness and sensation).

Brain Death

Brain death is a clinical diagnosis based on unresponsive coma with persistently absent brainstem reflexes due to irreversible brain disease (Chatrian and Turella, 2002). Formal protocols must be followed to establish this very serious diagnosis. In some jurisdictions, clinical criteria are sufficient and ancillary testing is optional; in others an ancillary test is mandatory. The ancillary test can be an angiogram or other study demonstrating absent cerebral blood flow, or an EEG showing electrocerebral inactivity. Note that electrocerebral inactivity by itself is not diagnostic of brain death, but may also occur with sedation, hypothermia and severe cortical damage with preserved brainstem function. Hence, the clinical diagnosis must be made first.

Because of the serious consequences, only properly qualified personnel should record and interpret brain death EEGs. The recordings must satisfy all technical requirements. These EEGs are never 'flat': interpretation must recognize and account for all artifacts before concluding that there is no detectable cortical activity (Chatrian and Turella, 2002).

Dementia

EEGs are often done for dementia that consists of a progressive deterioration of memory, insight, cognition, personality and behavior due to diffuse or multifocal cortical and/or subcortical brain pathology. Alzheimer's disease is the most widely known etiology, but there are many others. The EEG typically shows nonspecific background slow activity and other slow activities roughly corresponding to dementia severity. However, occasionally it may reveal more specific abnormalities, such as periodic patterns suggesting Creutzfeldt-Jacob disease or subacute sclerosing panencephalitis. Rarely, focal slow activity and/or asymmetry may raise the possibility of a potentially treatable structural cause, such as chronic subdural hematoma or brain tumor, but these possibilities are better evaluated by neuroimaging. Epileptiform

abnormalities may appear in dementia with or without a history of clinical seizures; rarely, seizure or status patterns may be encountered and modify medical therapy. A normal EEG might suggest pseudodementia due to depression, but can also occur in the early phases of organic dementias (Chatrian and Turella, 2002; Markand and Brenner, 2002).

Cerebrovascular and Structural Brain Disease

Stroke and brain tumor were common EEG indications in the past, but today modern neuroimaging provides superior anatomical assessment. Regional continuous slow activity and asymmetry consisting of reduced background rhythm amplitude are the hallmarks of focal structural brain lesions (Lüders and Noachtar, 2000; Zifkin and Cracco, 2002). However, the same abnormalities can be found with reversible functional disturbances, such as during a transient ischemic attack (TIA), or following a focal seizure or classical migraine with aura. Thus, it is important to remember that the EEG is a functional study and not an anatomical imaging test. Regional continuous slow activity and asymmetry with increased background rhythm amplitude ('breach rhythm') are characteristic findings after craniotomy. Deep midline brain lesions may be manifest by nonspecific generalized intermittent or continuous slow activity.

Sometimes the EEG can help differentiate between TIA and seizure. It may also identify epileptiform abnormalities or seizure patterns complicating stroke or brain tumor. Intraoperative EEG monitoring during carotid endarterectomy can guide selective shunting to minimize the risk of perioperative stroke.

Psychiatry, Psychology and Cognition

The concept that an EEG could objectively measure psychiatric disorders, psychological states or cognition is intuitively appealing since the underlying biochemical and synaptic processes might be expected to produce characteristic EEG patterns. However, while routine EEG can disclose epilepsy or other brain disease mimicking, complicating or contributing to psychiatric disorders and may show certain adverse psychotropic drug effects (Small, 2005), it has little more to offer psychiatric diagnosis or cognitive assessment because simply visualizing signals from 21 scalp sites cannot possibly reveal the vast and mysterious complexity of human thought and emotion (Gevins, 1998).

Nevertheless, a growing body of research indicates that more detailed analyses could measure some aspects of thought, emotion, and their disorders (Gevins, 1998; Altenmuller et al., 2005; Lopes da Silva, 2005). These methods involve computer processing, such as statistical frequency content analysis, autocorrelation, cross-correlation, cognitive evoked potentials, and other techniques best applied to 'high-resolution' recordings from many more scalp electrodes to increase spatial sampling (Gevins, 1998).

These fascinating approaches do show promise and might ultimately achieve some of their objectives, but none have yet reached mainstream clinical use for individual patient diagnosis. For example, they are not part of the criteria for mental or behavioral disorders in either the Diagnostic and Statistical Manual or the International Classification of Diseases (Small, 2005). In addition, according to the American Academy of Neurology and the American Clinical Neurophysiology Society, computer processed EEG remains investigational for mental and behavioral disorders and risks serious misdiagnosis when clinically applied by inexpert practitioners (Nuwer, 1997).

Conclusion

Properly recording and interpreting an EEG or ECoG requires suitable training and qualification. The basic principles and criteria for normal, benign variant, and abnormal patterns must be fully mastered and adhered to. The indications for diagnostic recordings include epilepsy, disturbances of consciousness, brain death, dementia, cerebrovascular or structural brain disease, and to a limited extent, psychiatric disorders. Monitoring is useful for selected patients with epilepsy or impaired consciousness and for some surgical procedures such as carotid endarterectomy. Some quantitative computer EEG analyses are useful adjuncts to expert waveform interpretation in selected neurological brain diseases. Efforts to apply quantitative EEG to psychiatric or cognitive assessments show promise but presently remain investigational.

Electronic Waste

Josh Lepawsky, Memorial University, St. John's, NL, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Electronic waste (e-waste) can be understood as the detritus of the information age. Yet, there are important historical and geographical reasons to consider a more nuanced understanding of e-waste. Historically, the electronic objects that are today treated as waste in places such as the United States and the European Union were explicitly treated as a source of strategic resources. Contemporary international trade in e-waste does not conform to a simple geography of dumping. A fuller understanding of e-waste entails fundamental ethical questions about learning how to live well together.

Introduction

Electronic waste (e-waste) can be understood as the detritus of the information age (a period of human history corresponding, roughly, with the rise of mass digital computing in the 1970s). Yet, such a definition hinders understanding of the historical contingency and geographical variation of practices through which electronics become waste. One might more accurately approach e-waste *qua* waste as an indexical possibility, that is, like the words 'here' and 'there' in the English language, e-waste as waste only comes to be waste in a situation in which it is enacted as such. Understood this way, e-waste is a contingent result of a conjuncture of specific and situated practices of ridding and the affordances, both material and informational, of digital things. What this means is that discarded electronics need not necessarily become waste.

The most common representations of e-waste today offered by environmental nongovernmental organizations (ENGOs), media, and the large majority of scholarly studies, frame the issue as a postconsumption problem characterized by electronics being dumped by rich Northern consumers on the poor of the global South. This seemingly straightforward narrative has arguably become the dominant story line of environmental politics (Hajer, 1995) surrounding e-waste. This dominant story line is predominantly framed by variants of the pollution haven hypothesis. The pollution haven hypothesis proposes that polluting industries have a propensity to agglomerate in those jurisdictions where environmental regulation is least costly and/or least stringent (J. Clapp, 2002). The dominant e-waste story line about rich countries and their citizens dumping their toxic e-waste on the poor countries such as Nigeria, Ghana, China, India, and Pakistan trades on a popular imagination of the pollution haven hypothesis. However, scholarly investigations of the hypothesis have shown inconclusive results (Lepawsky and McNabb, 2010). Some studies find support for the hypothesis while others do not, and some have documented improvements in various measures of environmental quality as foreign direct investment has increased over time.

Collectively, then, the assessment of the pollution haven hypothesis remains equivocal. Part of the reason for this equivocation relates to how the pollution haven hypothesis is typically framed (J. Clapp, 2002). Few studies, for example, examine waste processing and disposal industries. Instead the focus is on manufacturing and then often there is no comparative differentiation between industries that are more pollution intensive than others. Pollution haven studies also tend to measure direct pollution abatement costs while foregoing other important related costs (such as insurance, certification, and public relations) but which are difficult to measure across and between industrial sectors.

An examination of recently available data highlights the complexity of the international trade in electronic discards (**Figure 1**). For example, the largest flows are dominated by trade from the United States to Mexico, Canada, and the Republic of Korea (South Korea). The United States also exhibits a host of much smaller trade outflows to countries in Europe, but also in Central and South America (e.g., Nicaragua, Ecuador, and Brazil) and Africa (e.g., Nigeria, Congo, and Zambia) (**Figure 2**). However, a comparison with China highlights additional complexity to the story (**Figure 3**). China exports to several European countries (e.g., Germany, the United Kingdom, and Ireland), all of North America (Canada, the United States, and Mexico), but also to several Asian (e.g., Vietnam, Thailand, and Cambodia) and African countries (e.g., Nigeria, Ethiopia, and Tanzania). Despite China having a per capita income considerably higher in 2011 (The World Bank, n.d.) than some of its Asian and all of its African trade partners (making China the 'richer' country), all of these trades are permissible under the Basel Convention (as of 2013), the primary international legal arrangement governing transboundary waste flows. This is because China's trade with its Asian and African partners occurs between what the Basel Convention defines as non-Annex VII countries (non-Annex VII countries include all signatories to the Convention except for the Organization for Economic Co-operation and Development (OECD), European Union (EU), and Lichtenstein).

If attention is shifted back to North America, to Mexico, it is by far the poorest member of the North American Free Trade Agreement, yet it is also an OECD country and, as such, an Annex VII country under the Basel Convention, making it a legitimate trade partner with all other Annex VII countries (OECD, EU, and Lichtenstein) (**Figure 4**). Though dominated by imports from the United States, Mexico is also an exporter (though in much smaller volumes) to Canada, the United Kingdom, Qatar, and Guatemala – the latter two countries being non-Annex VII and thus, barring extant bilateral trade agreements with Mexico, illegal recipients of e-waste exports from Mexico under the Basel Convention.

These examples show that the international trade in discarded electronics does not conform to a simple image of

Figure 1 International trade flows of e-waste in 2010. Flow lines are read clockwise from source country to trade partner(s). Width of flow lines is proportional to weight in metric tons. Size of countries is proportional to number of export partners. Color of countries refers to their status under the Basel Convention: blue are Annex VII, red are non-Annex VII. Color of flow lines indicates the Annex VII status of a given flow's source country. See Lepawsky, J., McNabb, C., 2010. Mapping international flows of electronic waste. high-income countries dumping their waste in low-income countries. The next section of this article further explores the complexities involved.

Situated Histories and Geographies of 'the E-Waste Problem'

Discarded electronics have a history as 'e-waste' that is quite recent. It was reports from ENGOs that brought widespread attention to the issue (e.g., Basel Action Network, 2002; Toxic Link India, 2003). There was little, if any, public discussion of a thing called e-waste prior to these reports. Instead, electronics that were rubbish in Thompson's (1979) sense of the term were seen as a potential source of strategic metals and treated as scrap, rather than waste. As early as the 1970s, discarded electronics were being investigated not as waste but as sources of recoverable common and precious metals (e.g., aluminum, copper, and silver; Dannenburg et al., 1972; Kenahan et al., 1973; Kleespies et al., 1970). During this period, materials engineers were publishing technical papers on metal recovery from electronic scrap and the US Bureau of Mines experimented with precious metal recovery from electronic scrap from military and civilian sources.

Multiple factors motivated this research, including the passage in the United States of the Solid Waste Disposal Act of 1965 as well as concerns over resource scarcity. An important geographical and historical shift in what discarded electronics are occurred: what was once practiced as a resource in the United States decades later came to be practiced as waste there and elsewhere (e.g., EU). How and why this discursive shift occurred has yet to be studied in relation to e-waste, but it deserves scholarly attention since such an inquiry is likely to reveal much about how modes of wasting work and about the cultural, political, and economic practices that shape them.

There are recent hints that the nature of electronic discard practices is turning once again toward enacting it as resource (Schluep et al., 2009; Wang et al., 2012), but the organization of these practices is much different than those of the 1970s. Whereas then, manufacturing, consumption, disposal, and resource recovery was being done predominantly within North America and Europe, today a more complicated geography of value capture and creation is emerging vis-à-vis e-waste. Instead of approaching e-waste as a linear and necessary endpoint in a chain of production, consumption, and subsequent disposal, electronic discards circulate in nonlinear webs of possible wasting and valuing (Lepawsky and McNabb, 2010). Trade in such discards is international and largely undermines the common images associated with e-waste of it flowing from high-income countries to low-income countries. The bulk of such trade occurs within, rather than between these regions. It also sustains vast recovery economies (or 'good enough' markets, see Gadiesh et al., 2007) of resale, repair, refurbishment, remanufacturing, and reuse. In Dhaka, Bangladesh, for example, estimates suggest that as many as 60 000 people are directly engaged in the electronic discard recovery economy and the bulk of those discards are derived from within Asia (Lepawsky and Billah, 2011). Processing electronic discards under certain conditions can indeed be risky for workers' health and the environment, but this activity also comes with a wide range of benefits that cannot be ignored. Such benefits include broader access to technology, technological upgrading, skill and knowledge transfer, income, and the reuse of electronics, which dampens demand for raw material extraction. These potential benefits do not necessarily outweigh the risks, but they should be considered in conjunction with concerns about poverty, inequality, and justice.

Much evidence indicates that electronic discards from countries in North America and Europe end up in poorer countries of the global South. The dominant e-waste story line narrated by ENGOs and much media in North America and Europe (e.g., CBS, 2009; Höges, 2009; Klein, 2009) mutually reinforce this understanding of e-waste. This version of the story relies on evidence such as asset tags (labels of ownership that remain attached to discarded electronics) and forensic data analysis of hard drives found in processing sites. Without disputing the veracity of such evidence, questions are being raised about how representative it is of the range of sources from which electronic discards are derived. Yu et al. (2010), for example, offer projections showing that by 2015 the developing world will surpass the developed world in e-waste generation; and a recent empirical study in Ghana estimates that of the 'second hand' electronics imported into the country 15% are nonworking and enter the informal recycling system, whereas 85% are working and move into the resale, repair, and refurbishment markets (Amoyaw-Osei et al., 2011: pp. x–xi). The report also suggests that more than 50% of the total e-waste in the country is derived from domestic sources in Ghana. Similar results have been found in Dhaka, Bangladesh, where intraregional imports from elsewhere in Asia exceed those from North America and Europe (Lepawsky and Billah, 2011). Moreover, these imports sustain dynamic electronics discards recovery economies premised on resale, repair, refurbishment, and remanufacturing – an issue also highlighted by recent research at Agbogbloshie in Accra, Ghana (Grant and Oteng-Ababio, 2012; Oteng-Ababio, 2012), one of the sites singled out by ENGOs and media to support the dominant e-waste story line that focuses on dumping.

None of this is to suggest the dominant story line about e-waste narrated by ENGOs and media is entirely false, but it does trade on a number of unwarranted assumptions about e-waste as a matter of concern. These assumptions include that North American and European sources of electronic discards are more important than intraregional and/or domestic sources for the countries in which e-waste processing is occurring. There is, then, good reason to reconsider the dominant e-waste story line about rich Northern countries dumping e-waste in poor Southern ones.

Moreover, there is no necessary reason to restrict our understanding of e-waste to what happens to electronic devices after they are consumed and discarded. Indeed, doing so blinds us to crucial issues of waste generation from electronics manufacturing that occur long before consumers even purchase the devices of which they may eventually rid themselves. As early as the 1980s, for example, important work on occupational health and safety in the electronics manufacturing sector began to emerge that raised serious concerns about the health consequences of working with chemicals commonly used in the industry that make their way into workers' bodies and groundwater (Beall et al., 2005; Bender et al., 2007;

R.W. Clapp, 2006; LaDou, 1984, 1985, 1986). These chemicals do not become part of the manufactured item and as such are a remainder of manufacturing that must be managed.

Concerns over occupational health effects from chemicals used in the manufacture of computer chips led to the formation of the Santa Clara Center for Occupational Health (SCCOSH) in the late 1970s. SCCOSH later initiated a project called the Silicon Valley Toxics Coalition (SVTC, which later became an independent organization) in 1982 after evidence began to emerge that semiconductor manufacturing plants were releasing toxic chemicals into the valley's groundwater (Gabrys, 2011; see also Smith et al., 2006). As a consequence of SCCOSH's and SVTC's advocacy, the US Environmental Protection Agency eventually identified more than 20 sites in the valley that met the criteria to be defined as Superfund sites for cleanup. Silicon Valley thereby gained the dubious distinction of the most Superfund sites of any locale in the country.

In the 1990s, the advocacy work of SVTC expanded to include the Campaign for Responsible Technology (now the International Campaign for Responsible Technology), which expanded activism not only around toxins, but also groundwater extraction for chip manufacturing, especially in the expanding industry of the US Southwest. The 'clean-industry' image that had to that point been part of the Silicon Valley mythology was crumbling as a consequence, but notably these issues of toxic release and groundwater extraction were not framed as 'e-waste' as that term is typically used today. Others have examined the material and energy inputs of electronics manufacture (Kahhat et al., 2012; Kuehr and Williams, 2003; Williams et al., 2002, 2004) and note that this industry is an energy and materially intensive one, the products of which exceed by orders of magnitude the energy and material inputs of products in other industries, such as automobile manufacturing. Again, however, this use of energy and materials is not framed as wasteful, nor is it visible in the dominant e-waste story line.

Scholarly Debates

The contemporary scholarly debates about e-waste have developed several prominent foci including toxicology, management and processing techniques, and regulation. The toxicology literature has, in the first decade of the twenty-first century, documented a wide range of negative health and environmental outcomes associated with certain techniques of processing discarded electronics for their parts and materials. Potential health outcomes include toxic body loading (Ni et al., 2010; Tue et al., 2010), neonatal behavioral change (Y. Li et al., 2008, 2010), and diffusion of toxins into food supplies (Chan et al., 2012; X.-B. Zheng et al., 2012). Examples of negative environmental impacts include accumulation of toxins in proximate and distant ecosystems (F. Wang et al., 2009; J.P. Wu et al., 2011; H. Yang et al., 2012).

While there is no doubt that when processed under particular conditions discarded electronics are a source of toxic hazards, there are important controversies around this issue. For example, the processing and management literature typically confines itself to high-technology industrial processing techniques. Meanwhile, almost no research exists documenting and comparing different artisanal (often called 'primitive' in the dominant e-waste story line) processing techniques. Some of these techniques, such as open burning, do indeed result in highly toxic remainders. Images of open burning and open container hydrometallurgy (in which acid solutions are used to extract metal ores and which can easily lead to spills of toxic substances) often provide the pictorial evidence of the negative aspects of e-waste processing in ENGO documents and journalistic accounts. Yet such techniques are not used universally. Other forms of artisanal smelting such as the *bhati* process used in Bangladesh, for example, adapt technologies originally developed for smelting and metalworking to processing discarded electronics. This process involves small enclosed clay furnaces which, because they result in much higher temperatures than open burning, may lead to less toxic residues and emissions being produced (though this possibility has yet to be studied).

Questions also arise about the desirability and environmental consequences of industrial electronics recycling (Barba-Gutiérrez et al., 2008). Transport for collection and processing has its own environmental footprint. So too do the energy and material requirements of industrial scale recycling which typically shreds electronics in order to sort them into recoverable materials. Such practices destroy what, given the right conditions, may be perfectly workable equipment and components. In the process, they also result in the loss of all the energy embodied in manufactured electronics derived from, among other things, the mining of raw materials, the supply logistics of manufacturing inputs, and labor that went into building the electronics that are, after discard, subsequently run through a shredding machine and destroyed.

Another important theme in the e-waste literature is how it is or should be regulated and how transitions to more sustainable forms of e-waste management can be made. The main debates focus on what constitutes proper legal compliance, how responsibility for managing e-waste should be distributed, and how power inequities may be better adjudicated in transitions to sustainable e-waste management (Lawhon, 2012). The focus of the compliance literature is often the Basel Convention. Much controversy persists around interpretations of the Basel Convention, in large part due to ambiguities created by the Basel Convention itself. For example, contradictions exist between the definition of hazardous waste used in the Basel Convention and the definitions used by signatory countries. The Basel Convention contains provisions that allow transboundary shipments of hazardous waste between signatories as well as signatories and nonsignatories under certain conditions (i.e., when bilateral or multilateral trade agreements exist between countries). It simultaneously lists materials considered to be hazardous, many of which are relevant to electronics, and exempts many of those same materials because no standard tests exist to decide their toxic potential.

Further, the Basel Convention imagines a world divided up into two monolithic blocs of countries (Annex VII countries comprising the OECD, EU, and Lichtenstein vs non-Annex VII countries comprising all other signatories) in which the latter, non-Annex VII countries, are construed as all equally vulnerable to hazardous waste shipments from the former. Yet, the world of trade no longer conforms to such a division. Today (2013), far more discarded electronics are traded

between non-Annex VII countries than between Annex VII and non-Annex VII countries. Consequently, under the Convention countries as radically different as China, India, Singapore, and Kenya are lumped together as equally vulnerable to trade from Annex VII countries but not trade amongst themselves. Thus, under the Basel Convention it is perfectly legal for Kenya to receive hazardous waste from China, India, or Singapore.

Adjudicating the responsibility for managing discarded electronics is another important area of controversy in the scholarly literature (Lepawsky, 2012). Laws premised on extended producer responsibility (EPR) have been passed in many jurisdictions specifically to manage e-waste, though it is not a form of waste governance unique to managing electronic discards. EPR is supposed to shift the financial and/or physical responsibility for managing discards to those that produce them, in other words, the brand manufacturers of electronic products. The logic behind the approach is that shifting responsibility to producers will force them to internalize the costs of managing disposal of their products and thus incentivize them to create products that last longer and/or can be more readily recycled. In practice, however, EPR legislation for electronic discards rarely if ever achieves such cost internalization. Instead, the costs are borne by consumers of such technologies who, in an increasing number of jurisdictions, are required to pay fees at the time of purchase to cover the costs of subsequent disposal of their devices. This result is not necessarily negative in itself since an argument can be made that those who consume a particular class of manufactures should share some responsibility for the costs of their eventual disposal. Yet, it is not a coincidence that these costs have successfully been kept external from brand manufacturers who are not interested in seeing such costs negatively effect their profit margins.

While the distribution of responsibility for managing electronics discards is one source of controversy around their broader management, there is another more subtle but arguably more important issue at stake: what is and is not open to democratic debate. Despite the variety of e-waste legislation all but a narrow range focus exclusively on managing waste once it is already produced. In other words, the contemporary public discussion of what to do about e-waste is largely confined to what to do after it already exists. Almost no public discussion or regulation about what happens in the design or manufacturing of electronics occurs. An important, though limited, exception to this is the European Union's Reduction of Hazardous Substances (RoHS) directive. The RoHS directive does mandate against the use of specific materials with toxic potential (e.g., lead and mercury) in electronic products and so does affect how brand manufacturers design and build their products to a certain extent. But, mandating against such materials is a limited form of ameliorating the problem of electronic discards. For example, it does nothing to increase the likelihood that electronics will be longer lasting, more reusable, more repairable, or more recyclable.

The limitations of regulatory approaches like RoHS or the myriad e-waste laws enacted over the last decade is illustrated by recent design changes to Apple laptops highlighted by iFixit (Kyle, 2012), a website dedicated to do-it-yourself repair and reuse. In a step-by-step 'teardown' (i.e., disassembly to illustrate repairability) of a recent model of MacBook the website notes design changes from older models that include proprietary screws to prevent user access to the machine's internal parts, RAM chips soldered to the logic board making it impossible to swap in upgrades, a battery glued into the case (making it at best difficult to replace the battery when it fails), and a display that is a completely fused unit making it impossible to repair or replace parts of the display should they fail. It is notable that all of these design changes, which reduce the repairability and upgradability of these laptops were made after RoHS and EPR e-waste legislation have been in place in the EU and some North American jurisdictions for a minimum of 10 years.

Conclusion

Whereas the dominant story line about e-waste in the early twenty-first century is one of dumping in low-income countries by high-income countries, its historical geography is quite different. As a potential source of strategic metals, emphasis was placed on sources of electronics in North America, particularly in cities (Kenahan et al., 1973). As waste from electronics manufacturing, attention was concentrated on Silicon Valley, California, and some parts of the Southwest United States, especially in terms of groundwater extraction and contamination. All of this is to say that the things that now typically comprise e-waste as a matter of concern are rather different than those that comprised its historical–geographical antecedents. Discarded electronics are not the same thing now as they were in the past. Nor do they have the same geographies. Their ontology as waste is fluid, rather than fixed. What these different enactments of waste from electronics suggest is that the contemporary framing of e-waste as necessarily a postconsumption phenomenon is a highly particular framing of it, rather than a necessary one. Paying attention to the way that e-waste is framed as a matter of concern is critical, because that framing plays an important role in how the problem is construed as a problem and, consequently, in framing the solutions proposed to alleviate it.

Framing e-waste as a postconsumption problem means discussion and management practices are restricted to the issue of what to do with waste after the products that will constitute it have already been manufactured (see Gille, 2007). More effective solutions to the e-waste problem, even as it is so framed, requires reorganizing relations between production, consumption, and disposal. If the public discussion of e-waste remains confined to what to do with electronic discards after they already exist, then the prospects for enacting a safer world will be very limited. Individual consumers, households, businesses, and industries may divert more and more electronics away from landfills, but the longevity of those electronics, the ease with which they can be reused, repaired, refurbished, or recycled, the toxicity of the materials with which they are made, the conditions under which people labor to produce them, or the material remainders of manufacturing itself are unlikely to improve. Indeed, if the public discussion remains oriented toward end-of-pipe solutions, then, as Gille (2007: p. 210) argues, "the most that democracy can achieve is to regulate what to do with the wastes already produced." If a goal in solving the e-waste problem is to enact a world that is safer in terms of toxics and fairer in terms of labor conditions,

then the public discussion about e-waste *qua* waste must escape the end of the pipe and flow through the factory gates and into a discussion about how and with what materials that which will eventually be discarded is manufactured before it ever leaves the factory floor. Though such democratization of production, as Gille (2007) calls it, might sound utopic, experiments with regulating production and its discards along these lines are underway in other industries (such as fair trade certification of foods).

Though certainly problematic, such regulatory experiments demonstrate that the entrance of public discussion into conditions of production can and does occur. What such politics of production, consumption, and disposal tell us is that practices that enact electronic discards as waste (or as resource or as something else altogether) are 'worldings' (Haraway, 2008; Roy and Ong, 2011; Tsing, 2005), that is, actions that gather together otherwise unlike things – such as circuit boards, monitors, and CPUs with corporations, consumers, citizens, workers, labor conditions, and moral injunctions ('do the right thing') – and enacts them as if they all inhabit the same common world. Such worldings vis-à-vis waste cannot help but raise fundamental questions about what is good or what is to be done (Hawkins, 2006). E-waste *qua* waste, then, is an entry point into fundamental issues about learning how to live together well.

Eliade, Mircea (1907–86)

Robert A Segal, Lancaster University, Lancaster, UK

This article is reproduced from the previous edition, volume 7, pp. 4405–4409, © 2001, Elsevier Ltd.

Abstract

Mircea Eliade was a Romanian-born historian of religions who spent his last three decades at the University of Chicago Divinity School. He was one of the last great comparativists and was celebrated for his writings on the myths, rituals, and symbols of religions around the world. He was most celebrated for his lifelong defense of the approach to religion that characterizes the discipline of religious studies. Eliade maintains that religion originates to serve a distinctly religious end: providing contact with God. He assumes that, by contrast, all of the social sciences account for religion non-religiously: as serving some sociological, anthropological, psychological, or economic end. Eliade advocates the religious account over any social scientific account on two grounds: that the religious account coincides with the account offered by believers themselves, and, even more, that it alone satisfactorily accounts for, so to speak, the religious nature of religion. Eliade was influential outside of religious studies as well as within it. His attempt to find religiosity in the beliefs and activities of professedly atheistic moderns was especially influential.

Mircea Eliade was the best-known contemporary theorist of religion from the discipline of religious studies. He was one of a handful of scholars within the discipline who influenced scholars outside it. Unlike specialists in a single religion, he was influential as a theorist of religion as a whole. While he wrote specialized tracts on Australian religions, Indian religions, alchemy, yoga, shamanism, and the religion of his native Romania, he was most celebrated as one of the last comparativists and, even more, as the latest defender of the defining tradition of religious studies. Eliade sought to demonstrate the universality of religion by finding it in even seemingly secular domains. He also wrote fiction, and in Romania was a popular novelist and short story writer.

Life

Mircea Eliade was born in Bucharest on March 9, 1907. He began writing for Romanian weeklies as a teenager. In 1925, after completing the *lycée*, he entered the University of Bucharest and received an MA for his thesis on Italian philosophy from Ficino to Bruno. His mentor was the philosopher Nae Ionescu. While at university, he continued writing regularly – short stories, scholarly articles, reviews, and translations. He also founded a journal.

In 1928 Eliade went to India to study Sanskrit and Indian philosophy with Surendranath Dasgupta of the University of Calcutta. He aspired to become sufficiently trained linguistically to secure a professorship in comparative religion at the University of Bucharest – an especially ambitious goal since no chair in the field existed at the University at the time. Daring to hope that one would be created for him, he immediately immersed himself in Sanskrit grammar. He also discovered the world-affirming variety of yoga known as Tantrism. This outlook came to express Eliade's view of religion universally: that the sacred is to be found within the profane rather than outside it.

Impressed by Eliade's diligence and enthusiasm, Dasgupta soon took him into his household and treated him almost as an adopted son. When Dasgupta discovered that Eliade was having an affair with his 16-year-old daughter, Maitreyi, under his own roof, he threw Eliade out of his house, and the two parted ways forever. Undeterred, Eliade proceeded to spend six months in the ashram of Rishiskesh, learning the practice, not merely the philosophy, of yoga. Even during his time in India, which constituted his field-work, he recognized that his heart lay in comparative religion rather than in any single religion. While in India, he continued writing, turning out newspaper columns and magazine articles about his travels, scholarly articles on yoga, and several novels. After three years in India, he returned to Romania, pressured by his father to undertake his already deferred year of military service. He intended to return to India but never did.

Back home, Eliade worked on his doctoral thesis on yoga, which he had begun in India, and simultaneously published articles, wrote novels, worked for journals, gave radio talks, and organized public lectures – all on a host of topics. He came to be considered the leading cultural figure of his generation of young Romanians. In 1932 he did his year of military service, largely doing translations. In 1933 he received his doctorate. In the same year he published the novel *Maitreyi*, about his love affair with Dasgupta's daughter. The book won a prize and became a best seller. It was the Romanian literary sensation of 1933, and Eliade became famous.

At the end of 1933 Eliade began teaching at the University of Bucharest. He had hoped to be offered a lectureship but had to settle for serving as an assistant to Ionescu. He held the post for five years, lecturing on various topics in both religion and philosophy. Ionescu, whom he continued to idolize, was the intellectual mentor of the Iron Guard, the Romanian counterpart to the Nazis , and wrote diatribes against Jews. Proclaiming that Jews deserved to suffer because they had rejected Jesus as their savior, he demanded that Romania rid itself of all Jews by any possible means. In his autobiography Eliade self-servingly emphasizes his own break with Ionescu over the status of Jews, but recent research has uncovered scores of viciously anti-Semitic newspaper articles written by Eliade himself (see Berger, 1989; see, in reply, Rennie, 1996, Chap. 13). Eliade associated Jews with everything foreign to true Romanian

culture. In stock anti-Semitic fashion, Jews were blamed for communism, materialism, democracy, and modernity. Eliade's official biographer, M L Ricketts, uncritically accepts Eliade's own presentation of his position (see Ricketts, 1988, II pp. 903–912). According to both, the fervently Romanian nationalism that Eliade espoused was spiritual rather than political. The Government nevertheless arrested and detained Eliade in 1938 because of his zealous support for the Iron Guard. Eliade was subsequently transferred to a sanitarium.

In 1940 Eliade was allowed to leave the country to serve in the Roman Legation in London, and in 1941 he was transferred to the Legation in Lisbon, where he remained until the end of World War II. He returned only once to Romania. Had he returned after the war, he would have faced arrest as a collaborator. He left for Paris in 1945, where he spent 10 years writing the scholarly tomes that made him internationally famous. In 1946 he served as a visiting professor at the *Ecole des Hautes Etudes* of the Sorbonne. In 1956 he was a guest lecturer at the Divinity School of the University of Chicago, and the next year he became a permanent Professor of the History of Religions. In 1962 he was named the Sewell S. Avery Distinguished Service Professor. He co-founded the journal *History of Religions.* He became the best-known scholar of religious studies in the world and the leading advocate of the field. He retired in 1983, at the age of 76, and was honored with the establishment of an endowed chair in his name. He died in Chicago on 22 April 1986. Shortly afterwards, there appeared the culminating opus of his career: the 16-volume *Encyclopedia of Religion*, edited by him.

Theory of Religion

The tradition perpetuated by Eliade goes back at least to the nineteenth-century comparativists Friedrich Max Müller (1823–1900) and C. P. Tiele (1830–1902) and was continued by such figures as P. D. Chantepie de las Saussaye, Nathan Söderblom, Gerardus van der Leeuw, W. Brede Kristensen, and Raffaele Pettazzoni. This tradition, alternatively called comparative religion, phenomenology of religion, the history of religions, and, most simply, religious studies, maintains that religion is religion and little, if anything, else. Accordingly, religion is not the subject of anthropology, sociology, psychology, or economics. It is the subject of religious studies alone. The focus of religious studies is less on the truth of religion than on its origin and function. Religion, according to this tradition, arises for the distinctly religious purpose of making contact with God.

The tradition is, however, ambiguous about its aims. Sometimes it claims to be merely *presenting* the adherent's point of view, which purportedly deems religion a route to God. Other times the tradition claims to be *endorsing* the adherent's point of view. Now religion really does serve to make contact with God. The tradition thereby ceases to offer a mere description of religion and now offers an explanation, or a theory, of religion. But then the issue of the truth of religion proves difficult to sidestep. For if religion succeeds in making contact with God, God must exist.

Eliade's own position is unclear. He himself wavers between presenting and endorsing the believer's point of view. Typically, he declares modestly that 'The ultimate aim of the historian of religions is to understand, and to make understandable to others, religious man's behavior and mental universe' (Eliade, 1959a, p. 162). In contrast to the theologian, from whom he repeatedly distinguishes himself, the historian seeks only to explicate, not to advocate, the adherent's point of view: 'The procedure of the historian of religions is just as different from that of the theologian. All theology implies a systematic reflection on the content of religious experience, aiming at a deeper and clearer understanding of the relationships between God–Creator and man–creature. But the historian of religions uses an empirical method of approach. He is concerned with religio-historical facts which he seeks to understand and to make intelligible to others' (Eliade, 1959a, p. 88).

Yet in actuality Eliade ventures far beyond the mere presentation of the believer's point of view. He does not hesitate to discuss dead religions, whose adherents are scarcely available for consultation. His chief source of information for even living religions is not informants but their texts and practices. Moreover, he is prepared to grant that the meaning of all religions is partly, even largely, unconscious. Of religious symbols, for example, he states that 'we do not have the right to conclude that the message of the symbols is confined to the meanings of which a certain number of individuals are fully conscious, even when we learn from a rigorous investigation of these individuals what they think of such-and-such a symbol belonging to their own tradition. Depth psychology has taught us that the symbol delivers its message and fulfills its function even when its meaning escapes awareness' (Eliade, 1959b, pp. 106–107). Eliade goes as far as to assert that even most professedly non-religious moderns are in fact religious: 'The majority of the "irreligious" still behave religiously, even though they are not aware of the fact .... [T]he modern man who feels and claims that he is non-religious still retains a large stock of camouflaged myths and degenerated rituals' (Eliade, 1959a, pp. 204–205). Eliade outright bars any exceptions: '[E]ven the most avowedly non-religious man still, in his deeper being, shares in a religiously oriented behavior' (Eliade, 1959a, p. 211). In imputing to avowed atheists a religiosity of which they are wholly unconscious and which contradicts their own conscious one, he is doing more than describing the actor's point of view. His defense of his view of religion as irreducibly religious cannot therefore be that it is so for actors themselves. It must be that religion is itself irreducibly religious. He must be offering a theory, not just a description, of religion.

The aspects of religion on which Eliade focuses are myths, rituals, and symbols. All are means of encountering God. Religion for Eliade arises not from an encounter with God but from a *yearning* for an encounter. Religion provides both places and times for the encounter. It demarcates as 'sacred' those places, or spaces, where God has previously appeared. Adherents assume that God, who is elusive, will more likely appear where God has already been than in a new place. Even if adherents believe that God is everywhere, they still go to church to seek out God. Similarly, religion sets off as sacred those times, always long past, when God most often appeared. Because adherents believe that God was closest at hand during or just after creation, they use myths about creation not merely

to tell them when God was nigh but, more, to carry them back to that time: 'It is easy to understand why the memory of that marvelous time haunted religious man, why he periodically sought to return to it. *In illo tempore* the gods had displayed their greatest powers. The cosmogony is the supreme divine manifestation, the paradigmatic act of strength, superabundance, and creativity. Religious man ... seeks to reside at the very source of primordial reality, when the world was *in statu nascendi*' (Eliade, 1959a, p. 80). Myth works like a magic carpet.

In the tradition of religious studies, Eliade maintains that the quest for God, or the sacred, is not a means to an end but the end itself. Adherents seek the sacred because they seek the sacred, not because they seek something else through it. Religion can have anthropological, sociological, psychological, and economic benefits, but those benefits are considered to be only the consequences of a quest for the sacred and not the purpose of the quest. Furthermore, Eliade tolerates no reciprocal causality, the way, for example, Max Weber does. Religion can have non-religious effects, but not vice versa. Other scholars in the field of religious studies do allow for multiple causes as well as for multiple effects of religion, but they still insist that the main cause is the religious one. For the uncompromising Eliade, the sole cause of religion is religious. Somehow religion cannot arise for both religious and non-religious reasons.

Because Eliade pits the religious cause against all other proposed ones, he pits the field of religious studies against the social sciences, which he continually faults for accounting for religion non-religiously, or 'reductively': '... a religious phenomenon will only be recognized as such if it is grasped at its own level, that is to say, if it is studied *as* something religious. To try to grasp the essence of such a phenomenon by means of physiology, psychology, sociology, economics, linguistics, or any other study is false; it misses the one unique and irreducible element in it – the element of the sacred' (Eliade, 1958a, p. xiii). Eliade takes for granted that, as disciplines, the social sciences stand committed to a non-religious account of religion.

Only once, in all his writings, does Eliade qualify his condemnation of the social sciences as resolutely reductive in their approach to religion. In fact, the qualification comes in an otherwise unbending indictment of anthropologists for spurning the adherent's point of view, which he assumes to be religious: 'Indeed, as it is well known, the main interest of the western scholars has been the study of material cultures and the analysis of family structure, social organization, tribal law, and so forth. These are problems, one may say, important and even urgent for western scholarship, but of secondary importance for the understanding of the *meaning of a particular culture*, as it was understood and assumed *by its own members* (broader, sympathetic and intelligent studies like those of Marcel Griaulle, E. G. [sic] Evans-Pritchard or R. G. Lienhardt, and a few other cultural anthropologists are rather exceptional' (Eliade, 1967, pp. 502–503 [italics in original]).

Eliade's characterization of anthropology was outdated even when he wrote the essay, and it has become ever more outdated ever since. At best, his characterization, which borders on caricature, applies to the British brand of social anthropology influenced by A. R. Radcliffe-Brown. But the interest of British social anthropologists in social structure has rarely been at the expense of an interest in religion, as the cases of Evans-Pritchard and Lienhardt, as well as that of Radcliffe-Brown himself, conspicuously attest.

More important than the accuracy of Eliade's depiction of anthropology and of other social sciences is his argument. For him, the social sciences wrongly disregard the believer's point of view. But in fact they do not. Far from ignoring, let us even suppose, the religious nature of religion for adherents, social scientists begin with it. The actor's point of view constitutes the data to be accounted for. If social scientists ignored 'the meaning of a particular culture, as it was understood and assumed by its own members', they would have nothing left to account for. Why religion has meaning for adherents is what social scientists want to know.

Yet if social scientists necessarily turn to adherents for the data to be accounted for, they do not necessarily turn to adherents for an account of the data. Believers are akin to patients; social scientists, akin to doctors. It is not that religion is a disease to be cured but that religion is better understood by doctors than by patients. Patients may provide their own diagnoses of their ailments, but the final diagnosis rests with the doctor. That a patient rather than the doctor has the disease does not make the patient an expert on it. A patient's own diagnosis may turn out to be correct, but not because it is the patient's.

Eliade's indictment of anthropologists for spurning the actor's point of view is even more tenuous because as noted, he himself spurns it. If he is entitled to find a religious function in the professedly non-religious activities of avowed non-believers, why are social scientists not entitled to find non-religious functions in the professedly religious activities of avowed believers? In truth, both are entitled to venture beyond the actor's point of view.

Eliade's additional argument for accounting for religion religiously is that an account of any phenomenon must match the phenomenon being accounted for. Just as an account of a work of literature must be literary, so an account of a religious belief or practice must be religious. Eliade is right to insist on symmetry between an account and the subject of the account. But he is wrong to assume that the phenomenon being accounted for can be characterized and thereby accounted for in only one way. A 'literary' work such as a novel can alternatively be characterized as a work of history, sociology, or autobiography, and can then be accounted for accordingly. A Freudian account of religion characterizes a believer's relationship to God as a child's relationship to the child's father, and then attempts to account for that relationship psychoanalytically.

For Eliade to reply that God is more than a human being would miss the point. Freud never claims to be able to account for all aspects of God, only for father-like ones. He never claims that his characterization of the relationship between believer and God as filial is exhaustive. As a whole, social scientific accounts of religion claim at most to be offering necessary, not sufficient, accounts of religion. Freud recognizes the gap between a father and a God, and he is prepared to turn to religious studies to close it. He claims only to be demonstrating how father-like God is. Eliade, however, would bar Freud from offering an account, whether necessary or sufficient, of any aspects of God, and would do so on the question-begging grounds that religion is religion and not psychology.

Abstract

Starting with a biography of Norbert Elias (1897–1990), this article proceeds to outline his major work, *Über den Prozeß der Zivilisation*. While influenced by different strands in sociology, history, and psychology, the unique and major achievement of this work consists in linking developments on the level of individuals, i.e., the 'civilization' of conduct, manners, or display of emotions, to large-scale processes on the macro level (monopolization of state violence, longer chains of interdependence among human beings). Finally, the resonance this work and its author have found both within sociology and a wider academic audience is discussed.

Born on 22 June 1897 to Jewish parents in Breslau (now Wrocław, Poland), then part of Germany, Elias, after completing his secondary education, first set out to study medicine, but soon changed to philosophy. Only after having completed his dissertation in that discipline in 1924 did he turn to sociology, pursuing his studies at Heidelberg, then one of the leading universities in Germany. He was accepted by Alfred Weber, Max Weber's brother, as a candidate for the *Habilitation* (conferring qualification as a university lecturer or professor), but when his colleague and friend Karl Mannheim obtained a chair at the University of Frankfurt, Elias followed him in 1930 as his assistant. His thesis for the *Habilitation* was completed by the beginning of 1933, but with the Nazis having taken over power in Germany, Elias had to flee, leaving Germany first for France, and then, in 1935, for London, on a grant from a philanthropic organization. Between 1935 and 1938, he completed his now famous two-volume *Über den Prozeß der Zivilisation* (*The Civilizing Process*), which, as a book published in the German language on the eve of World War II, did not receive much attention before republication in 1969. Elias remained in England where he obtained a post as Lecturer in Sociology at the University of Leicester but not before 1954. After retirement in 1962, he spent 2 years as professor of sociology in Ghana. Later on, he moved first to Amsterdam and then to Bielefeld (Germany), and was also invited to a number of European universities as visiting professor during the 1970s. In the mid-1980s, he moved back to Amsterdam where he died on 1 August 1990 (on his biography, see Elias, 1990; Mennell, 1989). Only during the 1970s, after a few sporadic articles, had he begun to publish extensively, first in English and later on, during his Amsterdam and Bielefeld years, drawing much on older manuscripts, in German. Some of the manuscripts were published only after his death.

There are few sociologists for whom knowledge about their biography is as central in understanding both their fate as a sociologist and their influence on the discipline as in the case of Elias. His first major book, and by far the most influential one, was not recognized as a masterpiece before his retirement as a university teacher. During the 1950s and 1960s, Elias seemingly was cut off, and cut himself off, from his former German contacts, such as Theodor W. Adorno. Neither Elias nor those very few sociologists who acknowledged the outstanding achievement of *Über den Prozeß der Zivilisation* (e.g., Johan Goudsblom or Dieter Claessens) were successful in campaigning for this book. It only became famous in the early 1970s, when copies of the 1969 edition began to circulate among students and when a best-selling German paperback edition appeared in 1976. Translations into about 15 languages testify to the wide interest the book still attracts. Elias later complained about the insufficient recognition of the other works he published, among other subjects, on the sociology of sciences (Elias, 1974), on time (Elias, 1988), on relationships between the established and the outsiders (Elias and Scotson, 1965), on sports (Elias, 1970a), and even on topics such as Mozart (Elias, 1991a) or *The Loneliness of the Dying* (Elias, 1987a). Yet, without any doubt, *Über den Prozeß der Zivilisation* is by far his most important, and probably also his only truly original contribution to sociology.

This is not to say that this work, like his others, does not draw on many concepts and notions developed by fellow sociologists. The idea of conceiving of society in terms of processes, instead of states, the absence of which from contemporary sociology was a theme reiterated in Elias's writings from the 1960s onward, was firmly rooted not only in the work of those American and English sociologists, such as M. Ginsburg and W. Osgood, whom Elias began to study in London in 1935 (van Krieken, 1998: pp. 26–28), but also in important strands of German sociology, not least two thinkers whose work he was surely well acquainted with, Karl Mannheim and Alfred Weber. From the latter, he probably borrowed the notion of the civilizing process (Weber, 1920), but giving it an entirely different content, as Weber by that term referred to the continual accumulation of knowledge, conceived of as a transition from 'naiveté' to reflection and to mastering of nature (a theme that is not entirely absent from Elias's late writings). Other important influences that are easily recognized were Sigmund Freud and the Dutch historian Johan Huizinga, whose *Herfstij der middeleeuwen* (Huizinga, 1919) was Elias's dominant source on the late Middle Ages. But the blend Elias formed from these, and other ideas (such as Simmel (see Tabboni, 1993), or traces of Darwinism), together with his own research, was decidedly unique.

The main achievement lies in the rigor with which Elias portrays the development of certain forms of conduct or manners and ties this development to large-scale processes of state formation and modernization, on the one hand, and the

concomitant effects on the psychic level, above all the display of emotions, on the other. The first volume of *Über den Prozeß der Zivilisation*, drawing on a variety of etiquette manuals, lucidly describes how norms of conduct we now think as self-evident, such as our eating habits, or norms concerning bodily functions including nakedness and sexuality, gradually developed from the Middle Ages onward (with the selection of this 'starting point' not meant to imply that the process had not begun before that time). The Middle Ages are described as a time when man could answer needs and desires more spontaneously, when emotions were displayed with much less restraint. The gradual replacement of the use of fingers with forks and knives at the table, the diffusion of the idea that spitting or blowing one's nose onto the ground or into the fingers are to be considered embarrassments to others, or the refinement and suppression of violence – all these are examples of the change of outward, overt behavior in the direction of increasing 'civilization.' These changes are accompanied by a gradual shift of the psychic apparatus toward an increasing influence of the superego (especially feelings of shame and embarrassment), and also of the ego, over the human drives, or the id, and by a restriction of affects and impulses, a 'damping' of the amplitude of the swings of emotion.

These developments were, in the second volume of *Über den Prozeß der Zivilisation*, analyzed as embedded in large-scale historical processes. The rise of the European empires, especially French absolutism, and the concomitant development of monopolies of violence on the state-level restrained aggressive behavior in everyday conduct. The French court was also the site where the nobility developed those manners that were continually refined in the courtiers' competition for the king's favor (a process described in more detail in Elias, 1969). These manners also served as elements of distinction of the entire nobility vis-à-vis the *bourgeoisie* – but to no avail, as the latter, and later on also other social strata, began to imitate and to take over the nobility's patterns of behavior. These interdependencies are part of the overall process of modernization, especially of social differentiation, which requires of modern man a degree of reflection, foresight, and calculation unknown to medieval man. The distinctive overall characteristic of this process is the increasing internalization of social constraints, or the gradual replacement of 'outer' constraints by self-constraint – a self-constraint we are only sometimes conscious of, as it is routinized and habitualized, or incorporated, in our everyday conduct.

The main thrust of the book thus resonates well with a theme that has become central to the social sciences and the humanities in the 1970s: the investigation of domination, or constraint, not (only) on the (macro) level of relationships between social groups, but rather as it makes itself felt on the (micro) level of emotions and of individual conduct. It is a topic that can be found in the writings of Herbert Marcuse, or of Michel Foucault of the mid-1970s, who both echoed, albeit with very different emphasis (and seemingly without relating to Elias), the 'discontents of civilization' Sigmund Freud had already articulated in the late 1920s. Elias's account was perhaps received with even more sympathy as it nonetheless retained an optimistic tone. On the one hand, it was sensitive to the 'costs of civilization' that were felt by many at that time. On the other, Elias regarded the process of civilization as possibly leading to a balance between individual needs and the requirements of social life and in the long run to a more peaceful world society. The uniqueness of *Über den Prozeß der Zivilisation* has two (related) dimensions: In terms of content, it lies in its blend of sociology with historical and psychological insight. In terms of method, it lies in its linking of grand theory with careful scrutiny of detail.

Many sociologists would readily acknowledge that sociology has to look at historical processes; however, few, if any, have actually delivered a picture that so vividly describes the changes in people's manners and habits that have occurred from the Middle Ages onward. Elias gave a detailed description of how 'medieval man' (women are indeed largely absent from his account) gradually became 'modern man'; that is, where others have rendered snapshots, Elias has produced a movie, as it were. We can indeed understand that medieval man, as depicted by Elias (i.e., more impulsive, aggressive, and yielding more readily to emotions than modern man) is alive today, but in a more suppressed, constrained way.

This, together with its often lucid language, largely free of sociological jargon, has rendered *Über den Prozeß der Zivilisation* popular among a wider audience of nonspecialists. It has also been received well by historians such as Robert Chartier or Robert Muchembled, and also in psychology and other humanities. This is not meant to imply that Elias has triggered new research agendas in these disciplines; rather, his work was considered as congenial and as providing an overarching framework for research that had been devoted to similar topics, but without his broad, all-encompassing approach. At the same time, it is often concluded that by assuming a long-term trend toward 'more civilized' behavior, Elias possibly has drawn too far-reaching conclusions. While accusations of Eurocentrism in his work can easily be refuted, the observation that other cultures have developed comparable standards of civilization (in Elias's sense) remains a challenge to the theory (see, however, Mennell's (2007) recent attempt at analyzing 'The American Civilizing Process' in a manner quite analogous to that of Elias). It is also questioned whether medieval man indeed was so different. Certainly some of what Elias says on the display of emotions is valid; but the Middle Ages also had highly developed cultural rules for constraining and guiding behavior. A related problem is that Elias in the final analysis was not able to account for the cruelties of the twentieth century, not least those of Nazism. Elias certainly was aware of the ambivalences of civilization, but they were recognized by him mostly on the individual level, to the neglect of the dangers inherent in such seemingly civilized (and civilizing) forces such as modern technology or the state monopoly of violence. It must be added that during his late life, he became more sensitive to these issues, but still arguing fervently in favor of the possibility (not the unavoidability) of worldwide peace.

Elias's account exhibits serious lacunae also on the more factual level (van Krieken, 1989). Among the deficiencies of *Über den Prozeß der* Zivilisation is the absence of an account of the processes through which the manners of conduct, described by Elias only with reference to the etiquette manuals, were effectively brought about by (private, and later on public) educational practices. Even more importantly, some presumably decisive conditions of modern civilization (in Elias's understanding of that term) are entirely lacking.

Among these, most conspicuous are, first, the disciplinary mechanisms that were invented or became more widespread during the eighteenth and nineteenth centuries, especially the school and the factory, an observation that also points to the almost complete absence of the working class from Elias's work. Second, going further back in history, we also find a neglect of religion, certainly one of the most important sources of (European) civilization in the form of monastic discipline and more generally the religious prescriptions (and proscriptions), not least of Protestantism.

Elias's later theoretical work, claiming to develop a general 'theory of human beings' (*Menschenwissenschaft*), exerted little influence on sociology in general. The earlier focus on social processes in these later writings was complemented by more emphasis on the 'figurational' nature of society, a term coined by Elias to point out that man and society could and should be understood as relational entities (see especially Elias, 1970b, 1987b). With that concept, he claimed to overcome the alleged dichotomy of individual and society that he saw prevailing in most other sociologists' thought – an idea borne not so much from in-depth acquaintance with sociological theorizing but rather from his desire, obvious in most of his late works, to portray himself as a unique innovator of sociological theory. Figurations were analyzed mainly in terms of power – or more exactly of power differentials, of the dynamics resulting from these, and finally of the outcomes which, as he often argued, cannot be understood as a realization of the purposes of social agents but rather as unintended consequences. In other words, his sociology was mainly a structural-relational one, with emphasis on the dynamics of social relations (in contrast to much of the 1930s–60s structuralism). The price was a neglect of individual motivation as well as of broader cultural systems of meanings, such as values or norms. The absence of such aspects from Elias's sociology is perhaps a consequence of his reluctance, acquired very early in his grappling with philosophy, to concede that ideas have an existence of their own. Only in his latest writings did he start to acknowledge the influence of systems of meaning and language (Elias, 1988, 1991b). With respect to some sociologists' claim to apply or to extend Elias's figurational sociology, it must be borne in mind that he never developed anything approaching a systematic account. Therefore, references to this theory must be viewed as partly gratuitous, as the idea of a 'relational' sociology certainly is not Elias's original contribution.

In contrast, fruitful inspirations continue to come from his theory of the civilizing process. Research in this spirit is accomplished above all in those places where he spent the last two decades of his life, that is, the Netherlands, especially Amsterdam, and also Germany, whereas in the United States, in spite of a few admirers such as Lewis A. Coser or Thomas J. Scheff, his work has attracted wide attention. There have been fine extensions of the theory to specific phenomena such as eating practices (Mennell, 1985), the history of marriage (Schröter, 1985), the domestication of fire (Goudsblom, 1992), or the use of tobacco (Hughes, 2003), demonstrating how Elias's ideas are especially applicable to aspects of everyday cultural practices. But there are also attempts at rendering his approach useful to macroanalyses, such as in de Swaan's (1988) work on the development of modern welfare states. There is still much debate concerning the idea of civilization as an irreversible process and its relationships to modernity. While some researchers have explored the possibilities, and the conditions, of decivilizing processes, others have investigated processes of informalization, that is, the development of less restricted, destandardized norms of behavior (Wouters, 2007). Overall, it seems to be difficult to use Elias's ideas on the civilizing process as a starting point for really new developments; rather, much research focuses on applications of his insights to as yet unexplored phenomena, or on refining the theory in order to render it capable to account for phenomena that seem to contradict it at first sight.

The continuing interest in Elias's work is fed by the publication of his *Gesammelte Schriften* in German (Suhrkamp Verlag, completed in 2010) and his Collected Works in English (University College Dublin Press, not yet completed at the time of writing). Elias' correspondence and manuscripts are housed at the *Deutsches Literaturarchiv* in Marbach (Germany). The Norbert Elias Foundation, established by him in 1983, holds the copyright of all his published work and maintains a newsletter that reports biannually about activities related to Elias. These are entertained by a dedicated group of adherents to Elias, rightly described as a 'clan' or a 'family' by one of its members (Mennell, 2006). One can truly say that Elias has succeeded in establishing a 'school' of followers who both try to defend the achievements of their master (and their own) and to devalue other ways of doing sociology. At the same time, in some European countries there is still a market for Elias's work amongst a broader academic public; for example, a book published in France (Elias, 2010) catches attention with a red bellyband announcing '*Norbert Elias inédit*.' Thus, while Elias's influence on sociology as a whole may remain restricted, his work, and work in his tradition, will continue to constitute an important, if small, branch of sociology.

Abstract

Under confidentiality, identifiable data provided for statistical purposes is protected from unauthorized disclosure. Organizations acting as brokers between respondents and data users seek to disseminate useful data products while keeping low the risk of confidentiality disclosure. Recognizing that deidentification of each data record is generally inadequate to protect its confidentiality against attack by a data snooper, agencies restrict the data they release for general use. Typically, these restricted data procedures have involved transformation or masking of the original collected data through such devices as adding noise, topcoding, data swapping, and recoding. Another approach is to use the original data to determine a statistical model and use it to generate synthetic data. Generically, statistical disclosure limitation is a body of restricted data procedure that transforms data so that release of the transformed data adequately limits disclosure risk. Desirably, statistical analysis of the transformed data leads to inferences similar to that obtained by analysis of the original data. The technical procedures for implementation of disclosure limitation involve a range of mathematical and statistical tools.

Bayesian statistical and decision analyses require several inputs aside from observed data. Among these inputs are *prior distributions* and *utility functions* (Barnett, 1982), which typically reflect the opinion(s) of an individual or group. *Elicitation* is the process of encoding the subjectively held beliefs of an individual (called the *elicitee*) or group into prior distributions or utility functions. Elicitation is thus a complex (and imprecise) mapping from human knowledge processing to a quantitative metric. As such, the study of elicitation methods has two primary divisions – first, the psychological aspects of how humans are able to articulate knowledge, and second, the mathematical aspects of how such articulated knowledge is captured for use in a Bayesian analysis.

Subjective Opinion within a Bayesian Framework

Subjective opinion is actually employed in several parts of any statistical analysis, Bayesian or frequentist (Lad, 1996). The Bayesian model of decision making and inference is that prior beliefs about a particular attribute or state of nature are updated through data, and then used together with utilities to decide on a course of action. Formally, θ represents a (possibly multiattributed) state of nature such that $\theta \in \Theta$; $\mathbf{x}$ represents observed data; and

$f_\Theta(\theta)$	Prior
$f_X(\mathbf{x}\|\theta)$	Likelihood
$f_\Theta(\theta\|\mathbf{x}) = \dfrac{f_X(\mathbf{x}\|\theta)f_\Theta(\theta)}{\int_\Theta f_X(\mathbf{x}\|\theta)f_\Theta(\theta)d\theta}$	Posterior
$L(\theta, \mathbf{a}) = -U(\theta, \mathbf{a})$	Loss Function $(=-\text{Utility})$
$D(\mathbf{x}) = \min_a \int_\Theta L(\theta, \mathbf{a})f_\Theta(\theta\|\mathbf{x})d\theta$	Optimal decision minimizes posterior expected loss

Under a personal and subjective view of Bayesian inference sometimes called subjective expected utility (Savage, 1954), a decision maker will choose the course of action, a, that, based on prior beliefs updated by collected data, will have the least adversarial consequences when compared with other possible decisions.

Elicitation is concerned with mapping subjectively held opinions into prior probabilities, $f(\theta)$, and (subjective) preferences and value judgments into utilities (or exchangeably, loss functions) $L(\theta|a)$. These prior distributions and utilities represent an amalgamation of information available in addition to the data collected for a particular problem. As such, the most valuable elicited opinions are those of experts in the area of the problem, who may (or may not) have any training in statistical methods. Meyer and Booker (2000) and Chaloner (1996) outline reasons why subjective expert opinions are valuable in Bayesian analysis. These include the a priori information that can be quantified in the investigation of new, rare, complex, or poorly understood phenomena; when collecting large amounts of data is not feasible; when collected data alone is insufficient evidence for decision making; in designing experiments (*see* Experimental Design: Overview); in forecasting future events; and incorporating historical data and experiences that may not be well documented.

Spetzler and Staël von Holstein (1975) identify three stages of an elicitation process: the *deterministic phase*, which corresponds to choosing a functional form for a statistical model, the *probabilistic phase* where the subjective assessments are made, and the *informational phase* where verification checks are carried out. The primary focus of elicitation methods is on the middle phase (probabilistic). It is assumed generally, at least in statistical practice, that the first phase is fixed by the likelihood chosen for the data; the third phase is addressed more in the research on cognitive aspects of elicitation than the statistical aspects of encoding subjective beliefs and preferences.

Cognitive Aspects of Elicitation

In reporting subjectively held beliefs and preferences, there are several psychological heuristics that can lead to misrepresentation (*see* Cognitive Psychology: History). For more

detailed discussion on these, early work on the subject is found in Kahneman et al. (1982), Kyberg and Smokler (1980), Hogarth (1987); updated coverage is detailed in Poulton (1994) and in Wright and Ayton (1994). The most common problems in eliciting subjective opinions come from:

1. *Overconfidence*. Probability assessors tend to underestimate variability and the tails of the distribution.
2. *Hindsight bias*. Most assessors believe they would have predicted correctly the outcome of an event; thus only the outcomes that actually occurred are viewed as having nonzero probability of occurrence.
3. *Representativeness*. Expert judgments can be based on the synthesis of previously observed data. If that data came from small samples, it may not be representative. Other terms often used in conjunction with this heuristic are *base-rate neglect*, *small-sample fallacy*, and *misperception of randomness*. Another well-known aspect of representativeness is the *conjunction fallacy*, where higher probability is given to a well-known event that is a subset of an event to which lower probability is assigned.
4. *Availability*. The probability of an event is judged by the frequency with which an event can be recalled in memory. The classic example of this is in the elicitation of beliefs about likely causes of death; botulism, which typically gets a great deal of press attention, is usually overestimated as a cause of death, whereas diabetes, which does not generate a great deal of media attention, is underestimated as a cause of death.
5. *Adjustment and anchoring*. When an initial assessment is made, elicitees often make subsequent assessments by adjusting from the initial anchor, rather than using their expert knowledge.

To overcome possible biases introduced in the elicitation of probabilities and utilities by these heuristics, Kadane and Wolfson (1998) summarize several principles for elicitation:

1. Expert opinion is the most worthwhile to elicit.
2. Experts should be asked to assess only observable quantities, conditioning only on covariates (which are also observable) or other observable quantities.
3. Experts should not be asked to estimate moments of a distribution (except possibly the first moment); they should be asked to assess quantiles or probabilities of the predictive distribution.
4. Frequent feedback should be given to the expert during the elicitation process.
5. Experts should be asked to give assessments both unconditionally and conditionally on hypothetical observed data.

Eliciting Prior Distributions

Eliciting prior distributions entails quantifying the subjective beliefs of an individual into a statistical distribution (*see* Distributions, Statistical: Approximations). Kadane and Wolfson (1998) discuss the distinction between *structural* and *predictive* methods of doing this. In structural methods, an expert is asked to directly assess parameters or moments of the prior distribution; in predictive methods, elicitees are asked questions about aspects of the prior predictive distribution; the predictive distribution is

$$f_Y(\mathbf{y}|\mathbf{x}) = \int_{\Theta} f_Y(\mathbf{y}|\theta) f_{\Theta}(\theta|\mathbf{x}) \mathrm{d}\theta$$

and when no data has been observed (i.e., $\mathbf{x} = \{\varnothing\}$), this is known as the prior predictive distribution. In most complex problems, the predictive method is preferable, since it is more suited to the prescription for good elicitation methods outlined in the section 'Cognitive Aspects of Elicitation'. The functional form of the prior distribution is usually selected to be conjugate to the likelihood chosen to model the data.

The elicitation is generally executed by asking assessors to identify quantile–probability pairs (q, p) in some sense, where $p = P_X(X < q)$. Questions can be asked by specifying either a point or interval value for p or q, and responses can be given directly, as values, probabilities, or odds, or indirectly where preferences are stated between two alternatives.

To illustrate, consider various ways in which a prior distribution for the probability parameter in a binomial model might be elicited. The beta distribution is the usual choice for modeling the prior distribution, and functionally, the model is

$f_P(p\|\alpha, \beta)$	$\sim$ *Beta* (a, β)	Prior
$f_X(x\|p, n)$	$\sim$ *Binomial* (n, p)	Likelihood
$f_P(p\|\alpha, \beta, x, n)$	$\sim$ *Beta* $(\alpha + x, \beta + n - x)$	Posterior

In this instance, x is the number of successes observed in n trials; from the way in which the prior parameters are updated by the posterior distribution, $\alpha + \beta$ can be viewed as a 'prior sample size' or measure of prior strength, and $\alpha/(\alpha + \beta)$ as a point estimate of the mean prior probability of a success. So one way to structurally elicit a prior would be to ask an elicitee to specify a prior sample size and probability of success, and this would uniquely define the parameters of the prior distribution. This, however, does not provide any feedback to the elicitee, and will almost surely be overconfident because of the way in which the variability of the distribution is never elicited directly. It also does not address the issue of the skewness of the distribution. Chaloner and Duncan (1983) propose a predictive method for eliciting this same prior distribution, where the elicitee is asked to specify the modal number of successes for given prior samples sizes, and then is asked several questions about the relative probability of observing numbers of successes greater than or less than the specified mode. The elicitee is also shown (graphically) the implied predictive distributions for future observations specified by their current answers, and then walked through a bisection algorithm to adjust the spread of the distribution.

While the predictive method just described is more difficult to implement, it is also more appropriate in terms of having the elicitee answer questions that will effectively allow them to communicate both their knowledge and their uncertainty within the constraints of the model. To illustrate, suppose that in the structural method, an elicitee specified a prior sample size of 15 and a prior mean of 1/3. In the predictive method, the same elicitee specified, for a sample size of 15, a predictive mode of five successes; the odds of observing four rather than five successes was specified as 0.8, and the odds of observing six rather than five success was specified as 0.7. The two priors, in the structural case, a beta (5, 10) distribution, and in the predictive case, a beta (9.67, 18.74), are shown in **Figure 1**. This illustrates that way in

which the predictive method allows for better representation of the actual state of knowledge the elicitee has.

Existing protocols for eliciting prior distributions are described in some detail in Kadane and Wolfson (1998). Elicitation protocols are described as being either *general* or *application-specific*. General methods are those that are meant for specific classes of models, such as the beta-binomial, the normal linear regression model, the dirichlet-multinomial, and others. Application-specific methods are ones tailored to the problem under study; several examples of these are described both in Kadane and Wolfson (1998) and French and Smith (1997). Application-specific methods are used typically for complex situations, where there may be no conjugate or standard prior that is suitable, or where the elicitation process must be *decomposed* in order to provide sensible assessments.

Eliciting Utilities

The ultimate goal of eliciting utilities is to make decisions that minimize expected loss, under the constraints of uncertainty specified by the prior distribution and likelihood function. Determining expected loss means constructing loss functions that consist of outcomes based on a quantity of interest, $\mathscr{Q}$, and the loss associated with each outcome. The loss can be fixed or random. In general, there is a set $\mathscr{A}$ of possible actions that can be taken, and for each element of $\mathscr{A}$, there are losses that may or may not depend on $\mathscr{Q}$. The set $\mathscr{A}$ must be exhaustive; in other words, all possible actions must be enumerated, and each action must be exclusive of every other action.

The first stage of the elicitation process should be to choose the action set $\mathscr{A}$ and the quantity of interest $\mathscr{Q}$. The set of actions should be well defined and must contain at least two elements. These actions are usually dependent on some quantity of interest. For example, if the action set consists of choosing which family planning program to implement, the quantity of interest might be some quantification of the state of infant mortality. In choosing the quantity of interest, it is important to make sure that $\mathscr{Q}$ is a quantity that incorporates the uncertainty inherent in the problem under study.

Figure 1 Structural and predictive elicited distributions for the beta-binomial model.

Generally, $\mathscr{Q}$ will be a random quantity defined by a statistical model, and as such, it can have several dimensions.

Once the action set $\mathscr{A}$ and the quantity of interest $\mathscr{Q}$ have been determined, the second stage of the elicitation is to construct loss functions based on them. This is the most difficult stage of the elicitation process. If several stakeholders are involved in the decision-making process, they may construct these separately or as a group; regardless, those assessing the loss functions must give careful thought to the consequences resulting from each action in $\mathscr{A}$ for any value of $\mathscr{Q}$. For useful overviews of loss function elicitation strategies, see works by Clemen (1996), Zeleny (1982), Edwards (1992), and Saaty (1980). In general, it is necessary to specify the form the loss functions should take; this is sometimes specified in advance, but it is advisable to consider this as part of the elicitation process.

There are several 'standard' loss functions. One of the best-known examples of a loss function is the 0–1 loss function generally applied to statistical hypothesis testing. In this case, the set of actions is given by $\mathscr{A} = \{a_1\text{: reject the null hypothesis}, \ a_2\text{: do not reject the null hypothesis}\}$ (Berger, 1985). An extension of this is the 0–k loss function, which is typically written (letting $\mathscr{Q} = \theta$)

$$L(\theta, a_i) = \begin{cases} 0 & \theta \in \Theta_i \\ k_i & \theta \notin \Theta_i \end{cases}, \quad i = 1, 2$$

There are many possible variants on this loss function that could be considered, and identifying the 'form' of the loss function is the more controversial of the tasks that must be performed in eliciting utilities. Given the conceptual framework of a 0–k loss function, consider the next elicitation task – identifying the values of k_1, k_2. Because k_1, k_2 can represent rather intangible quantities, it is often advantageous to specify their relative rather than absolute values. Consider that the 'optimal' decision in this example is to choose a_1 when

$$\frac{k_1}{k_2} > \frac{P(\theta \in \Theta_2|\mathbf{x})}{P(\theta \in \Theta_1|\mathbf{x})} = \frac{P(\theta \in \Theta_2|\mathbf{x})}{1 - P(\theta \in \Theta_2|\mathbf{x})}$$

Then the remaining elicitation task needed for decision-making is to elicit the ratio k_1/k_2, which simplifies the elicitation task from eliciting k_1, k_2 directly or independently. The ratio on the right-hand side above can be viewed as the ratio of the posterior probabilities that the parameter lies outside the 'rejection region' ($\theta \in \Theta_2$) to the posterior probability that the parameter lies within the region (or $\theta \in \Theta_1$). From this, a general relationship can be drawn between the functional form of the model and the two quantities for which preferences need to be elicited; this is illustrated in Figure 2.

Exploiting the relationships between the functional form of the model and loss function and the quantities about which preferences and value judgments must be elicited is a useful strategy. Many examples of the application of evaluating utilities and preferences are found in journals in the fields of risk analysis, accounting, and economics.

Other Issues

It is sometimes advisable or necessary to elicit the opinion of more than one individual. Genest and Zidek (1986) review

Figure 2 A decision maker should choose a_1 or a_2 based on the values of $P(\theta \in \Theta_1)$ and k_1/k_2.

methods for combining the opinions of several experts; Cooke (1991), Meyer and Booker (2000), and Morgan and Henrion (1990) provide guidelines for structuring elicitation tasks with groups of experts. French and Smith (1997) have several examples of analyses where elicitation of more than one expert is used. In general, there are two approaches used in group elicitation – the collective opinion of the experts is elicited in the whole or the opinions of several experts can be combined in some fashion.

Another issue that is discussed in the literature (see Kadane and Wolfson, 1998 for further discussion) is that of validating and comparing elicitation methods. There are several criteria that might be considered; the most important of these is *coherence*, that the elicited opinions obey the laws of probability (*see* Probability Theory: Formal). In general, this should be considered a minimal requirement for any elicitation method. Other considerations are the *reliability* of the elicitation methods in producing stable reflections of the elicitee's beliefs and preferences; also, the elicitation method can be validated by an examination of whether it obeys *proper scoring rules* (i.e., does not systematically encourage the misrepresentation of beliefs and preferences). Some practitioners of elicitation, particularly in the field of meteorology, advocate the *calibration* of expert opinion, whereby elicited opinions are adjusted to reflect the elicitee's ability to correctly predict events. Subjective Bayesians typically object to calibration because subjectively held beliefs and preferences are not meant to be infallible. A final consideration given in the validation and comparison of elicitation methods should be given to the modeling of errors-in-elicitation. Some cognitive aspects of this are described in Poulton (1994), but very little statistical literature is available on the subject.

Elites, Anthropology of

Hugh Gusterson, Elliott School of International Affairs, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Elites have been little studied by anthropologists because of practical and temperamental barriers to fieldwork. Early work on elites (in Africa, Oceania, South Asia, and Latin America) situated them in the context of broader social wholes and emphasized the importance of kinship in defining and maintaining elites. Subsequent work highlighted the roles of colonialism and capitalism in creating new elites – based on access to capital, education, and bureaucratic perquisites – that challenged and hybridized with traditional elites. While bureaucratic industrial societies present themselves as meritocracies, elites devise strategies of heredity dependent on their privileged access to the educational system and cultural capital. Anthropologists have only recently become interested in 'studying up' in the US, having earlier ignored the public debate of the 1950s and 1960s on the alleged 'power elite' in the US. Some of the most striking new work on elites has been of scientists, bankers, journalists, evangelists, psychiatrists, and development bureaucrats. Such work often requires innovative approaches to fieldwork.

'Elites' have been undertheorized and understudied in the social sciences, and the term has a certain vagueness: both 'traditional' and 'modern' societies are said to have elites, despite their divergent political and economic structures, and the privileges of elites may be grounded in genealogy, land ownership, control of capital, bureaucratic position, educational attainment, or religious status, for example. Analysts influenced by Marxism tend to emphasize the material underpinnings of elite status while those tilting toward Weber are more interested in elites' command of authority and prestige (Bottomore, 1993; Khan, 2012; Milner, 2014). Meanwhile some commentators treat the term 'elite' as broadly interchangeable with 'ruling class,' while others – making elite status more contextual – lend the term a fractal quality: subordinate classes and groups may have their own internal elites (skilled laborers, for example), so that society is honeycombed with elites all the way down. Thus one can forgive Richard Fox (1985: 931–932) for complaining that "the breadth of the elite concept comes at the expense of theoretical integrity."

The theorization of elites is often traced back to the Italians Vilfredo Pareto (1935) and Gaetano Mosca (1960), each working independently in the late nineteenth and early twentieth centuries to develop an alternative to Marx's theory of hierarchy in modern society. Pareto in particular saw the hereditarian elites of old Europe as prone to degeneration over time, and hoped that elites in capitalist societies would provide a meritocratic basis for social stratification. Despite their influence on sociological discussions of elites, especially as a counterpoint to Marxian discussions, the work of Pareto and Mosca has been of less interest to anthropologists.

In fact, anthropologists have historically shown relatively little interest in theorizing or studying elites. Early anthropologists were more interested in developing holistic descriptions of entire societies than of fractional segments, and they tended to be drawn to societies with relatively little division of labor. However, even as anthropology moved away from its early emphasis on holistic representations of non-Western societies, elites have still received relatively little ethnographic attention. There are many reasons for this, including practical obstacles, the historical conventions of the discipline itself, and the temperamental preferences of anthropologists. Elites are busy, important people who have the power to elude or obstruct anthropologists, and whose lives are usually unsuited to the anthropologist's classic (and time-intensive) technique of investigation – participant observation (Hertz and Imber, 1995). (While it is easy to imagine anthropologists helping peasants with the harvest, spending hours with poor womenfolk while they cook and clean, or idling with urban street-corner society, it is harder to imagine them sitting unobtrusively at board meetings, loitering in the hallways of the upper floors of the Pentagon, or being repeatedly invited to dinner with the Rockefellers). Anthropologists have also continued to neglect the study of elites for reasons of convention: the traditional division of labor in the social sciences has given anthropologists dominion over the geographically and socially marginal, and anthropology has historically developed as a discipline that explains to the center the logic of lifeways on the periphery. This convention retains a certain force even in the era of repatriated and postcolonial anthropology. There is also, finally, for many anthropologists a temperamental obstacle to fieldwork with elites: the traditional anthropological methodology of participant observation has historically demanded of anthropologists a reflexive sympathy for the people they have studied – largely poor and marginal people. This, combined with the liberal politics of most anthropologists, makes fieldwork with elites psychologically unappealing and conflictual (Gusterson, 1997).

Insofar as earlier generations of anthropologists wrote about elites, they often studied them not so much as topics in their own right but as components of larger social wholes or as products of social processes that were themselves the principal object of analysis. Examples include Dumont's (1970) work on caste, Barth's (1959) monograph on patron–client relations among the Swat Pathans of Pakistan, Kuper's (1961) study of an African aristocracy, and Sahlins' (1958) work on chiefs and followers in Polynesia. Insofar as this made elite status a processual outcome rather than a thing in itself, this was all to the good. Marcus (1983) observes that such work on elites tended

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12061-6

to cluster in particular ethnographic zones where kinship – the core subject matter of early anthropology – was particularly important in understanding the dynamics of elite status: South Asia, marked by its caste system; the Pacific Islands, home to hereditary chiefs and 'big men'; Africa, peopled by hereditary chiefs and kings; and the oligarchies of Latin America. Work by first wave anthropologists emphasized the importance in sustaining elite status of kinship relations, marriage strategies, land inheritance, patron–client relations, and ritual – what we might call the preindustrial sinews of elite power.

As colonization, industrialization, and missionization transformed societies around the world, new sinews of elite power emerged. Accumulation of capital (not just land) became increasingly important, as did access to education, geographical mobility, and positions in the expanding bureaucracies of new states. In many colonial societies the power of traditional, usually hereditary, elites was challenged by the rise of new elites who owed their standing to Western education, positions in emergent state bureaucracies, and trading opportunities provided by the colonial encounter. The processes of decolonization and globalization produced rivalries between emergent and established elites with different relationships to metropolitan power centers but, over time, old and new elites often hybridized through, for example, intermarriage, the conversion of capital into land, and a turn to Western education (Billig, 2007). (This process broadly reenacted a similar development that took place in the industrializing societies of Western Europe where the ancient aristocracies and rising bourgeoisies learned over time to accommodate to one another through marriage, education, and financial alliance). Processes of elite formation and mutation under and after colonialism are discussed by Ferguson (1990), Geertz (1963), Leach and Mukherjee (1970), Luhrmann (1996), and Vincent (1971).

As societies become more complex, bureaucratized and marketized, the bases of elite power shift and new kinds of specialized elites (from physicists and lawyers to investment bankers) emerge. One of the distinguishing features of complex industrial societies is that they have a more pluralistic constellation of elites than do their predecessor societies. Moreover, if the dominance of elites in 'traditional' societies was often expressed in direct, face-to-face contexts, elite dominance in industrial society is increasingly mediated by bureaucracies, investment markets, and educational systems, distancing elites from those below them. And if the privileges of elites in 'traditional' societies were often brazenly hereditary, reproduction of elites in industrial societies is, in theory at least, less regulated by kinship. Thus, Marcus (1989) and Marcus and Dobkin (1992),who has studied traditional elites on the Pacific Island of Tonga and dynastic families in the US, argues that, while kinship appears to define the transmission and reproduction of elite status for the Gettys just as much as it does for the Tongan aristocracy, the analogy is superficial and deceptive: for families such as the Gettys kin relations of inheritance constitute a shell that conceals the corporate and bureaucratic character of the contemporary dynastic family dependent, as it is, on lawyers and money managers for its functioning and reproduction.

Cohen (1981) points out that in industrial, bureaucratic societies recruitment to elites is generally advertized as meritocratic, yet principles of heredity often find a way to suborn processes of promotion ostensibly based on merit as members of elites transmit their privileges to their children. For example, private schools become a means of converting the wealth of one elite generation into the superior educational attainment of its children, allowing the circumvention of the meritocratic prohibition on the simple inheritance of elite position (Baltzell, 1987; Khan, 2011). Moreover, as Bourdieu (1986) and Lamont (1992) argue, elites come to value taste and manners as signs of distinction when recruiting a new generation of leaders, and accomplishment in this realm is asymmetrically transmitted to the children of existing elites as they are subjected to esoteric training in manners and taste in informal social contexts within the family, in private clubs, in peer groups, and at private schools. Secret societies, such as the freemasons and the fraternities at elite universities in the United States, can also play a role in short-circuiting the processes of meritocracy (Armstrong and Hamilton, 2013).

Anthropologists engaged in fieldwork in Western societies for many years tended to ignore Western elites. Thus, for example, anthropologists in the 1950s and 1960s kept out of the lively, at times bitter, debate in sociology and among public intellectuals provoked by the publication of C. Wright Mills' (1956) argument that, far from being a meritocratic society governed by a plurality of separate elites, the United States was ruled by a single 'power elite.' According to Mills this elite class was loosely integrated by the backstage functioning of private schools, elite universities, private clubs, and the marriage market and had become adept at disguising from the mystified masses its privileges and its degree of integration. Instead of joining this debate on elites in US society, American anthropologists engaged in fieldwork at home at this time were busy writing about 'the culture of poverty' or, in a logical sequel to earlier fieldwork abroad, studying processes of acculturation and economic struggle in Western enclaves of ethnic migrants from Third World countries.

A milestone in the recognition of asymmetries in the anthropological gaze came with the publication of Laura Nader's celebrated (1969) article calling on anthropologists to 'study up.' Nader drew attention to the problems of imposing a special visibility on the poor and powerless and appealed to anthropologists to shine an ethnographic spotlight on the functioning of power in the United States. Her article is often misrepresented as a call for anthropologists to engage in bounded studies of elite cultures, where in fact she called for studies of 'vertical slices' of social life that would enable the analysis of hierarchical relationships between elites and others and dramatize the essential nature of those relationships for the grounding of elite status and power. This was a way of reworking the traditional holism of anthropology. However, if the first generation of anthropologists had subordinated the study of elites to the analysis of societies as social wholes, Nader's is a call for holism that puts the privileges and power of elites front and center.

Nader observed that 'studying up' would probably require modifications of anthropology's fetishized research technique of face-to-face participant observation, and this has indeed proved to be the case (Stryker and Gonzalez, 2014). Given that elites are often mobile, busy, protected by minders, resistant to being studied, and expensive to socialize with, it is unlikely that

they can be studied using the same techniques anthropologists have developed for peasants, hunter-gatherers, and the urban poor. In order to study elites effectively anthropologists are having to rethink traditional notions of bounded field sites (Marcus, 1995), and to weave naturalistic personal interactions with their subjects together with archival and media research, use of big statistical data, online interaction, and formal interviews with informants too busy to meet more than once – a research strategy I refer to as "polymorphous engagement" (Gusterson, 1997). Examples of ethnographic studies of elites that depart from conventional methodological norms include Harding's (2000) study of the powerful American preacher, Jerry Falwell, which evoked the world he had created without access to Falwell and his aides; Rose's (1989) highly literary response to Nader's call to study 'vertical slices' of American life, juxtaposing miniaturized vignettes from the lives of poor African-Americans in Philadelphia with scenes from the lives of business elites and the country gentry in Pennsylvania; Vine's (2011) study of decisions by the US and the UK military elites to take a Pacific Island from its inhabitants, which makes use of archival sources and formal interviews, as well as participant observation with the displaced islanders; Aldrich's (1997) autoethnographic study of the Rockefeller dynasty, of which he himself is a member; and the sociologist Jennifer Pierce's (1995) study of a law firm by means of covert fieldwork conducted under cover of employment as a paralegal – a strategy that violates the ethics code of the American Anthropological Association if not the American Sociological Association.

Some of the most interesting work in recent years in the ethnography of elites has explored the practices of financial elites, elite taste cultures, and the world of scientific elites. This work has been undertaken in a context where, as many theorists of neoliberalism have observed, the global capitalist economy is increasingly financialized, increasingly dependent on a burgeoning new class of knowledge producers, and increasingly marked by levels of social and economic inequality that have not been seen in the West for a century (Castells, 2009; Gouldner, 1979; Harvey, 2007; Piketty, 2014).

One might think that bankers and financial traders would be the most inaccessible of elites to ethnographic study, but three fine studies, all by younger female anthropologists, take readers deep inside the highly masculine world of financial elites, exploring how they are recruited and socialized and what they do at work, how their work has been transformed by digital technology, how they have remade the corporate world through leveraged buyouts, how they come to believe they deserve multimillion dollar bonuses, and how their practices helped produce the near meltdown of the global financial system of 2008 (Ho, 2009; Tett, 2010; Zaloom, 2010).

Financial elites sit at the top of an increasingly unequal socioeconomic system where the wealthy are withdrawing into enclaves that are spatially segregated (Low, 2004) and aesthetically marked. Building on the work of Bourdieu (1986) and Lamont (1992) on the use of taste cultures by the wealthy to build networks and invisible barriers to socioeconomic mobility, a number of studies have explored elite taste cultures. Two of the most widely read have been sharply observed quasi-ethnographic studies by the journalists David Brooks (2001) and Robert Frank (2008). Beal (2000) and Czegledy (1998) analyze the mansion-building strategies of Jordanian and Hungarian elites respectively, parsing their careful hybridization of Western and local aesthetics, while Steiner (1994) and Myers (2002) track the international art market that transforms indigenous art work from Africa and Aboriginal Australia into objets d'art that signal the worldly sophistication of the global elites that purchase them. Wulff (1999), also working at the intersection of elite culture and aesthetics, writes on the culture of international ballet dancers.

Some of the most rigorous and innovative ethnographic work on Western elites has appeared in the new field of science studies. Perhaps because of their academic culture, scientific elites have proved unusually amenable to ethnographic study. Many ethnographic studies of scientists probe the symbolic prestige of science and the means by which scientists exercise their special license to declare what is true. Latour and Woolgar (1979) show how biologists make their claims authoritative; Traweek (1988) explores the cultural authority of particle physicists in Japan and the United States, while Gusterson (1996) examines the culture of American nuclear weapons scientists, and Helmreich (1998) documents the world of scientists at the elite Santa Fe Institute, and the way seemingly obscure scientific experiments may anchor and replicate dominant political ideologies. Luhrmann (2000) has written a powerful study of the socialization of American psychiatrists – an increasingly important category of expert in the production of American culture and identity. Meanwhile, exploring the scientific endeavor most productive of new wealth, Rabinow (1996, 2002) and Sunder Rajan (2006) have penned studies of the conjoining of venture capital and scientific entrepreneurship in the biotech industry's remaking of the world. This new wave of studies of elites still leaves gaps. One gap concerns political elites. Weatherford's (1981) study of the US Congress is now over 30 years old. While Wedel (1999, 2011) has written important studies of the transnational elites that manage the global development machinery and of patronage practices among the American political class, we need more studies of the way political elites function in the United States and elsewhere. That means studies of lobbyists, regulators, elected representatives, political consultants, and others. And, Bickford (2011) notwithstanding, we need more studies of military elites. In a world that is powerfully constructed by media, we also need studies of media elites and their relationship to financial, military, and other elites. Pedelty (1995) has written a vivid account of the journalistic elite that shaped Western understandings of wartorn Central America in the 1980s, exploring the ways in which these journalists' articles are shaped in response to the interests of elites both in Central America and in the United States, and Hannerz (2004) explores the culture of foreign correspondents more generally, but we also need studies of television and radio journalists, Hollywood productions, and of the elites who own media.

The ethnographic study of elites has the potential to stretch anthropology methodologically and theoretically, and to illuminate the hidden mechanics of an increasingly unequal global society. Anthropologists have historically gone into opaque cultural settings and rendered them transparent to their audience. If one of the crutches of elite power is invisibility, anthropologists have an important potential contribution to make to democracy and public discourse, as well as to

anthropological scholarship, in adapting and redeploying their traditional methodology for the study of elites.

Abstract

The term 'elite' was introduced to the vocabulary of the social sciences in the late nineteenth century by Vilfredo Pareto. Pareto, Gaetano Mosca, and Robert Michels developed classic elite theories in opposition to the Marxist belief that a popular proletarian regime would yield democratization. A ruling minority, so the basic theorem goes, will always out-organize large majorities. Contrary to the classics, the social sciences since World War II have mostly treated elites and democracy as reconcilable. Technical terms such as 'strategic elites' (Keller) were widely used to refer to incumbents of top positions in the various social sectors. The 'functionalist' or 'pluralist' school of thought departs from the idea of heterogeneity. 'Critical elite theory' claims that, even in modern democracies, economically based social hierarchies are reproduced, thereby giving rise to a single dominant class.

Long before the term 'elites' was coined, the concept had been used by various thinkers. Already Plato (*c.* 380–360 B.C.E./2002) imagined in *Republic* (book VII) a state ruled by philosopher-kings ('kings of a hive, better and more perfectly educated than the rest'). Plato's justification of such a rule is that philosophers only have knowledge of what really is, e.g., just or good. That genuine philosophical knowledge is needed for ruling, is the primary thrust of his argument.

Niccolò Machiavelli (1469–1527), an Italian diplomat who is commonly regarded as a predecessor of the classic elite theories, used the terms 'nobles,' 'aristocrats,' or 'the great' interchangeable to describe society's elite. In *The Prince*, Machiavelli (1531/2005) makes several recommendations for acquiring, governing, and preserving principalities in response to the political crisis of Italian city-states, including his own city-state of Florence: a prince should be both loved and feared; he needs able advisers; his best fortress is the loyalty of his subjects; and cruelty can be legitimate to maintain order. In a famous passage, Machiavelli advises the prince to emulate both the fox and the lion, cleverly outmaneuvering his foes ('find out the Snares') and courageously standing up against enemies ('fright away the Wolves'). In this first European secular treatise on politics, elites are considered as a threat to democracy, in the sense that they will bias the actual enacting of laws in their own interest. Machiavelli advises princes to base their power on the majority of citizenry rather than on the wealthy elite. His early ideas on power-checking mechanisms to constrain elites have been taken up in modern democratic theory (MacCormick, 2011). Classical elite theory adopted, among other things, not only the lion and fox metaphor, but also the idea that different styles of leadership were related to the rise and fall of elites as well as the conviction that self-ishness is a natural property of the human species.

Henri de Saint-Simon (1760–1825), a French utopian socialist, developed his ideas on those at the apex of social hierarchy with the French Revolution fresh in mind. He argued that the landed aristocracy ceased to be the dominant class and that its place was taken by entrepreneurs, financiers, and scholars – people whose importance derived from function rather than status. Saint-Simon illustrated this vital point when speculating on the loss to society if the best 'three thousand scientists, artists, and artisans of France' were taken away: "The nation would become a lifeless corpse … It would immediately fall into a position of inferiority compared with the nations which it now rivals, and would continue to be inferior until this loss had been replaced, until it had grown another head" Saint-Simon (1819/1964: 72).

Like Saint-Simon, other leading aristocratic critics of mass tendencies did not refer to 'elites,' although their ideas on large-scale processes of massification were established along the juxtaposition of the 'noble man' and the 'mass man' (Ortega y Gasset). The French social psychologist Gustave le Bon (1841–1931) and the Spanish philosopher José Ortega y Gasset (1883–1955) were both concerned with the crowd/the mass of the mediocre entering fields of decision-making (Le Bon, 1895/1897; Ortega y Gasset, 1929/1957). The 'era of crowds' (Le Bon) was suspected to result in cultural degradation and deterioration. Human excellence, it was ascertained, was only to be found in a few and not the many. Society itself was seen as aristocratic in its very nature: it can never be the many, the average, the mass, who rule. Mass, then, referred primarily to the quality of human beings and their numbers rather than to social class. Elites, in contrast to the masses, share a superior moral and psychological makeup.

The term 'élite' first appears in an encyclopedia published in France between 1751 and 1772 and edited by Denis Diderot (*Encyclopédie, ou dictionnaire raisonné des sciences, des arts et des métiers*). The encyclopedia entry suggests that the word was originally used to describe exquisite, top-of-the-line products and that its usage was later extended to designate membership in a superior social group ('*hommes d'élite*'). The term was, however, only introduced to the vocabulary of the social sciences in the late nineteenth century. A first broad definition of 'elite' in the social sciences is to be found in *Trattato di sociologia generale* of 1915–19 (translated as *A Treatise of General Sociology*) by the Italian economist Vilfredo Pareto (1848–1923):

> Let us assume that in every branch of human activity each individual is given an index which stands as a sign of his capacity, very much the way grades are given in the various subjects in examinations in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03079-8

> school. The highest type of lawyer, for instance, will be given 10. The man who does not get a client will be given 1 – reserving zero for the man who is an out-and-out idiot …. So let us make a class of the people who have the highest indices in their branch of activity, and to that class give the name … of élite.
>
> Pareto (1916/1935: 1422–23)

Pareto himself did not make any further use of this abstract concept. However, the idea that what counts are the skills and activities that people bring to their work was later taken up by functionalism, making Pareto their main precursor.

Classic Elite Theorists

The classics in elite theory were fierce opponents of Marxism (Bottomore, 1993). First, they criticized it for establishing a theory of socioeconomic development upon a single principle, which is the struggle between the unpropertied working class and the property-owning class. In their view, one has to take a multicausal approach to the study of human history instead of pursuing any deterministic 'single-track doctrine' (Mosca). Second, they denied that a classless society, as envisaged by most socialists, could ever be attained by arguing that minority domination is an inescapable feature of human life. Third, they challenged the view that primarily economics and not politics were the determining force in history.

Mosca: The Ruling Class

Gaetano Mosca (1858–1941) posits in his work entitled *Elementi di scienza politica* of 1896 (translated as *The Ruling Class* in 1939) that social change is determined not by class structure but by the political apparatus and an organized minority in control of this apparatus. Regardless of the type of political organization, this minority imposes its will on the disorganized majority. Mosca's argument hinges crucially on the paired terms 'organized' and 'disorganized.' He acknowledges that the ruling class in a parliamentary system will normally be divided into two or more competing parties and that the election outcome may have an effect on government policy. It is simply, however, that there will always be a discrepancy between *de iure* and *de facto* authority, or between formal political structure and informal political power, whatever democratic mechanisms may be employed (Femia, 1993). For Mosca (1896/1939: 53), the key to elite control lies in the minority's organizational capacity: "A hundred men acting uniformly in concert, with a common understanding, will triumph over a thousand men who are not in accord." He adds, however, that ruling minorities are endowed by 'a certain material, intellectual, or even moral superiority' (Mosca, 1896/1939: 53). It is not genetic heredity that contributes to the superiority of character, but special personal qualities, manners, habits, and wealth, which are inherited from similarly endowed ancestors. The intergenerational transfer of wealth and educational privileges especially tends to transform the rulers into a hereditary caste.

Despite this hereditary basis of power, the political class does not simply rule by force but always endeavors to justify its power in the eyes of those being governed by a set of values, the 'political formula.' In a Machiavellian fashion, Mosca thus emphasized the need for a moral basis to maintain power. He was convinced that political change originated from conflicts within the elite and not between elite and mass. It is, however, only in his criticism of Marx that Mosca draws a sharp distinction between the mass and an organized minority, while for the most part he presents a more subtle depiction in which he distinguishes between the top governmental leaders and a lower stratum consisting of high-level civil servants and others. The latter serves as a bridge between the ruling class and the rest of society. Despite a preeminent 'aristocratic' tendency to recruit members from the ruling class itself, parts of the lower stratum are granted access to positions of power and amalgamate with the elite ('democratic' tendency). The most enduring social organization is thought to be a mixed government (partly aristocratic, partly democratic), so that the political class does not atrophy or become unstable through a lack of continuity. In that way, the efficacy of government would go hand in hand with a certain measure of accountability to the interests of the people as a whole. A stable society could only be maintained if all 'social forces,' that is, all major institutional spheres such as religion or education, are represented within the uppermost class of society.

Pareto: The Governing éLite

Instead of 'ruling class,' Vilfredo Pareto (1848–1923) introduced the term 'élite' in his 1916 work *Trattato di sociologia generale* (translated as *A Treatise of General Sociology* in 1935), in order to avoid the Marxist intellectual baggage of the former term. In an initial, broad definition, 'élite' encompasses all individuals with the highest ranking in their social activities based on their skills and regardless of their moral and social qualities. Pareto, however, does not indicate where he thinks a feasible cutoff exists for separating the elite from the nonelite. Most likely, he abandons this formal definition because, in reality, a certain ascriptive status, along with wealth and birth, give the less skilled an advantage for attaining leading positions. In a more narrow definition, he subdivides the class of maximum performers into 'governing' and 'nongoverning' sections, the first of which includes all individuals who 'play directly or indirectly a noteworthy role at the highest levels of power' (Pareto, 1916/1935: 1423). How the governing elite, which is not necessarily marked by superior ability, goes about its job, is not specified. Like Mosca, Pareto is convinced that all societies are ruled by organized minorities, also in parliamentary democracies, and that only the elites are responsible for change, not the masses.

Pareto places particular emphasis on psychological characteristics as the basis of elite rule. Notably, Pareto employs Machiavelli's lion and fox typology by applying it not only to alternative control strategies but also to changing elite psychologies. Famously, Pareto theorized that fundamental distinctions can be made among the governing elites according to the predominate 'residues,' with residues being – roughly speaking – nonlogical propensities rooted in people's basic aspirations and drives. Within an elite, these are classified as either 'Class I' residues ('instincts of combinations') – innovative men skilled in intrigue and possessing cleverness in negotiation, the 'foxes' in Machiavelli's language – or 'Class II' residues ('persistence of aggregates') – conservative men with

strong sentiments of order and discipline, the 'lions.' Just as individual atoms form molecules in nature, so, too, did Pareto group individuals upon the basis of common 'residues' (Marshall, 2007: 33). Pareto specifically conceived of residues as manifestations of human sentiment. Residues are thus not thought of as concrete realities, but as concepts created by the observer, which implies, for example, that a man's (hidden) taste for pork chops does not fall into the analytical category 'residues.' If, however, a man constructs a theory according to which the Chinese cuisine is superior to the American, Pareto would suggest analyzing the (irrational) residues underlying this theory (Coser, 1977: 391).

While politics requires both sets of qualities, 'Class II' residues tend to weaken over time. One of Pareto's key arguments is that there is a constant circulation of individuals within the governing elite. Elites decline, degenerate, and die, sometimes at a fast rate, sometimes slowly: "It flows on like a river, never being today what it was yesterday. From time to time sudden and violent disturbances occur. There is a flood - the river overflows its banks. Afterwards, the new governing élite again resumes its slow transformation" Pareto (1916/1935: 1431). History, in Pareto's words, is a 'graveyard of aristocracies.' Typically, new elites seizing power consist of lions who are eventually replaced by more cunning foxes who, in turn, meet their destiny in the form of new lions, and so on. Change for Pareto is cyclical, not linear, and it is change that maintains the equilibrium in a system.

Michels: Political Leaders and the 'Iron Law of Oligarchy'

"It is organization which gives birth to the dominion of the elected over the electors, of the mandataries over the mandators, of the delegates over the delegators. Who says organization, says oligarchy." This postulate, spelled out in Robert Michels' 1911 seminal book *Political Parties* (1911/1999: 365), became encapsulated in the thesis of the 'iron law of oligarchy.' It essentially posits that democracy contains an oligarchical nucleus because even the most democratically committed organizations, such as the Social Democratic Parties in Europe studied by Michels (1876–1936), become divided into elite fractions who pursue their own interests within the organization by merely exploiting the labor and resources of the average party members. By declaring that the exercise of political power is an inherently oligarchic enterprise, Michels implicitly assumes that the elite, or rather the oligarchs, are characterized by what Meisel (1958) called the '3 Cs': group consciousness; group coherence; and conspiracy, that is, a common will to action. Structural forces, or more precisely, the 'technical indispensability of leadership' (Michels, 1911/1999: 364), push parties, like any other large-scale organization that has moved out of amateurishness, toward oligarchy. A political party needs to organize its vote, canvass supporters, raise contributions, attend to its financial structure and legal standing; all these activities require hard-to-acquire expertise and scarce organizing talents that limit the capacity of the party's rank and file to challenge elected leaders' decisions or to replace the leadership, while the leaders recognize a common interest in steering the organization and maintaining their position. Due to the '3 Cs,' lower level protest is hobbled, conservative loyalists promoted to the party staff, and power inexorably concentrated in the higher echelons of bureaucratic hierarchies. Psychological forces, such as the oligarchs' desire for power and the masses' psychological need for leadership, supplement the resulting estrangement between the leaders and the led. Michels puts himself clearly in a Machiavellian tradition when he writes that the 'the desire to dominate, for good or evil, is universal' (Michels, 1911/1999: 206), and he suggests a modified version of Pareto's circulation of elites when speaking of the 'réunion des elites' (Michels, 1911/1999: 182): one group of elites does not replace another. Rather, there is an ongoing process of power-sharing pacts, with established elites absorbing and assimilating newcomers.

Despite the fact that classic elite theorists had not developed a clear elite concept and most of their arguments were overly general and lacking concrete substance, they succeeded in providing bearings for empirical elite research that became centered primarily on four major topics: elite profiles, elite recruitment, elite change, and elite cohesiveness (Aron, 1960: 272). Mosca, Pareto, and Michels, who regarded themselves as empirical social scientists rather than social philosophers, were either ambivalent or outright critical of democratic movements: from their standpoint, an elite-dominated 'democracy,' in which career politicians impose themselves on the voters, is the most that is possible (Best and Highley, 2010). The degree to which these thinkers discredited themselves by their attitude toward fascism differs. Mosca, a member of the Italian Senate, took to the floor on different occasions to argue against law bills endorsed by the fascist leader Benito Mussolini. Pareto, an engineer who turned to economics later in life, welcomed the advent of fascism, although fascist ideologists did not find much merit in his works (Cirillo, 1983). The sociologist Michels converted from a revolutionary socialist to a fascist ideologue and accepted a chair of politics from Mussolini's government. Later defenders of elite theory clearly distanced themselves from the 'Machiavellians' and Michels by primarily arguing that the role of elites is not irremediably opposed to a substantial degree of democracy.

Pluralist Elite Theories

Mannheim, Dahrendorf, Dahl, Keller: Functional, Strategic Elites

After World War II, the social sciences generally shared the basic functionalist assumption that modern societies are characterized by structural differentiation and thus focused predominantly on the pluralist elite structure, in which the various meritocratic subsystems (the economy, politics, media, etc.) develop their own distinctive status hierarchies, with different elite positions linked to the apex of power. Elites are thus primarily those with power and resources at their disposal, thanks to professional achievement (Khan, 2012). The emergence of these autonomous elites was perceived as central to the foundation of democracy (Etzioni-Halevy, 1990). Arguably, the most important precursor of pluralist elite theories is the German sociologist Karl Mannheim (1893–1947). Although Mannheim noted that it was "the important contribution of modern democracy that the achievement principle increasingly becomes the criterion of social success" (Mannheim, 1935/1940: 86), he interpreted,

somehow paradoxically, the general public participation as having a deleterious effect on societal elites. Mannheim feared that the increased size of the elite, the 'proletarization of the intelligentsia,' as well as inter- and intraelite conflicts could deprive society of the continuity it needs; therefore, he offered an elitist solution to the threat of 'negative democratization.' Education should promote unity in the age of massification by instilling a sense of group cohesiveness and a common *Weltanschauung* within future democratically orientated elites.

Similar to Mannheim, Ralf Dahrendorf (1929–2009) contended that there are multiple elites in industrial societies. In his theoretical approach, society consists of a plurality of interest groups, which engender a plurality of conflicts. Elites are theorized as 'quasi-groups' (Dahrendorf, 1962: 310) and thus as a loose formation of individuals who occupy positions that have the same role interests. If latent common interests become conscious goals, then elites can turn into 'conflict groups.' Originally, Dahrendorf (1962) distinguished between the prestige upper class, the economic upper class, and the ruling class, or power elite. In his later work, however, all three quasi-groups are classified as elites without any differentiation (Dahrendorf, 1972: 126–136).

The American political scientist Robert A. Dahl (1915–2014) moved beyond classical elitism by discrediting any ruling elite model as quasimetaphysical; instead, he supported that of a polyarchy. For Dahl, social structure was not analogous in shape to a single pyramid, but to a range of pyramids. He argued that only a careful examination of a series of concrete decisions could establish the dominance of a specific group within a nation or community. Consequently, in his work *Who Governs?* (Dahl, 1961), he studied three political issues in New Haven, Connecticut, namely, party nominations for local elective offices, public education, and urban redevelopment. Dahl found no signs of a single elite operating behind the scenes but rather many lines of cleavage and politicians who were responsive to the desires of the citizenry.

Finally, Suzanne Keller (1927–2010) coined the term 'strategic elites' to refer to multiple, nonintegrated groups with power in the diverse arenas of modern society. Her underlying orientation is akin to the structural functionalism of Talcott Parsons. Strategic elites compromise "not only political, economic, and military leaders, but also moral, cultural, and scientific ones. Whether or not an elite is counted as strategic does not depend on its specific activities but on the scope of its activities, that is, on how many members of society it directly impinges upon and in what respects" (Keller, 1963/1991: 20). Elites, in this sense, are those with sustained social impact. These 'strategic elites' overwhelmingly act in accordance with the functional requirements of their status (i.e., the political elite is primarily responsible for deciding the goals to be pursued). Individual achievement and not class background is the chief principle for recruitment to strategic elite positions. Keller stresses cohesiveness regarding values as the key to the effectiveness of 'strategic elites.' Goals may differ, but value consensus among elites is theorized as a prerequisite for prosperity.

The majority of social scientists today endorse pluralist theories of elites, with various nuances and variations. Common to all is the argument that power is dispersed rather than concentrated in the hands of a few.

Critical Elite Theory

Mills, Bourdieu: Power Elite, Field of Power

Not surprisingly, pluralist elite theories have come under fire. In his provocative work *The Power Elite* (1956), C. Wright Mills (1916–62), a radical in spirit, argued that American society is controlled by single cohesive elite that constitutes the leadership of three major areas of society: military, business, and government. These three elites only appear to be separate. Due to the similarity of their social origins, close personal and family relationships, overlapping cliques between the principal power holders in each sector, and institutional proximity, those in different higher circles "conceive of themselves to be, and are felt by others to be, the inner circle of the 'upper social classes'" (Mills, 1956: 11). Mills preferred the term 'power elite' over 'ruling class,' because the latter term was judged to be a 'badly loaded phrase' as it did not give autonomy to the political order (Mills, 1956: 277). In a Marxist interpretation, the ruling capitalist class not only controls society's wealth but also decides on a society's political policy. By contrast, Mills believed that power has shifted from the owners of the means of production to managers and functionaries of the principal institutions of American society, such as high-ranking politicians. Members of the power elite are consequently defined as those 'in command of the major hierarchies and organizations of modern society,' who have the power to make decisions of national and international consequence (Mills, 1956: 4). Moreover, Mills subdivides the American power structure as a whole into three levels: (1) the close-knit power elite, an alliance between the highest military, corporate, and political leaders; (2) the middle level of power, meaning local elites, members of Congress, judges, pressure groups, and other organized groups; and (3) the virtually powerless, economically dependent and unorganized masses. In essence, those on top issue orders, which obedient administrators at the second level transmit to the population at the third level. Nearly all of Mills' assertions on the American power elite have been criticized as exaggerated or unproven (Dahl, 1958).

The French sociologist Pierre Bourdieu (1930–2002) discards the substantialist notion of 'ruling class' or 'elite' in favor of the relational concept of 'field of power' (Bourdieu and Wacquant, 1993). The field of power is the locus of struggle between agents who already hold dominant positions in their respective social fields, such as art, politics, or the economy. In this general space, France is the state that particularly but not exclusively exercises influence over the interrelations between specific fields because it holds a monopoly on the educational field and thus controls the entry points into all other fields. Within Bourdieu's theoretical framework of capital forms, the topological notion of 'field of power' enables various internal divisions resulting from struggles over which particular type of capital should be recognized as the most important. Drawing on extensive empirical studies, Bourdieu (1989/1996) creates in *State Nobility* a topology of the French educational system, especially the elitist *grandes écoles*, and relates it to the internal structure of the field of power. By applying correspondence analysis to 84 institutions, he discovers two striking homologies between both fields. First, the difference between major and minor schools reflects contrasts between the *haute bourgeoisie* (industrialists, private sector executives) and the *petty*

bourgeoisie (business owners, technicians, school teachers). Second, the animosity between the more academic schools (such as the *École normale supérieure*) and schools explicitly established to train its students to assume power positions (such as the *École des hautes etudes commerciales*) reproduces a fissure within the dominant class that separates the cultural from the economic bourgeoisie.

In general, Bourdieu identifies the *grandes écoles* not only as power institutions of the elite, but also as fortresses of isolation, which are just as difficult to leave as to enter. He shows that the social and family factors dictate not only the choice of more or less esteemed educational institutions, but also how the criteria of university examiners reflect the values of the dominant classes. From an analysis of a survey of winners of a national high school academic competition (*Concours Général*) and other sources, Bourdieu finds that these gate keepers in elite institutions rely on vague contrasts (brilliant versus dull, gifted versus motivated) that systematically discriminate against lower class pupils and thus contribute to the reproduction of class inequalities via the educational system.

Synopsis

The concept of elites has a long and checkered history. Initially, it was used to describe the rule of a minority over the majority of the population. Associated with it were usually rather vague meanings as 'fewness' and 'excellence.' Precursors of classic elite theory like Ortega (1929/1957) used dichotomies such as 'noble man' versus 'mass man' to refer to the few of noble spirit who place great demand upon themselves in the pursuit of excellence, on the one side, and the many ordinary men who are not concerned about individuality and consider themselves equal to everyone else, on the other. The category of 'mass' is not socioeconomic and class based; it is primarily intellectual excellence that marks the elite. Mosca gives the concept a different twist by introducing the term 'ruling class,' which essentially refers to an organized minority who monopolizes the decision-making power in society. He imagined the members of the 'ruling class' as leaders of excellence who could promote the moral and material interests of a society. Pareto defined elites as persons with the highest capacities in their field. These elites have to be efficient to stay at the top, that is, they must make optimal use of scarce resources to best benefit society. Such efficiency demands different styles of governing that range from adaptive politics (elites strong in class I residues) to aggressive and authoritarian measures (elites strong in class II residues). Finally, Michels was concerned with the emergence of oligarchs within complex, large-scale organizations that allow people in top positions to monopolize organizational means.

Most contemporary concepts of elites depart from a simplified juxtaposition of 'mass' and 'elite.' The pluralist school of thought emphasizes that, with the increasing differentiation of societies, power is dispersed among multiple leadership groups who bargain and compromise over key societal decisions. To identify a unique elite becomes impossible. Society is conceptualized instead as a number of parallel pyramids, each capped by an elite who hold the largest share of a given resource. These elites are accountable to public scrutiny and open to people from all social strata. Mills' concept of the 'power elite' differs from the prevailing pluralist vision on elites because it implies that few upper class people are essentially able to control very different societal sectors. Bourdieu also stands apart because he posits that the dominant class is able to maintain its traditional claim to key leadership positions in society. His work on the French 'state nobility' shows that the acquisition of exclusive educational degrees opens the door to top positions in companies for the few who are already in privileged social positions and discriminates against the many who are less privileged.

All elite concepts, although different, have some similarities. Each concept deals with the criteria of distinction and the sources of power of the elites. Table 1 offers a systematic overview of these rather hidden commonalities.

Table 1 Different Meanings of the Elite Concept

	Criterion of distinction	*Source of power*	*Domain*
Ortega	Intellectual excellence	No power	Society
Mosca	Excellence	Number of organizations	Society
Pareto	Efficiency	Force and consent	Society
Michels	Position within the organization	Monopoly in the use of organizational means	Complex organizations
Pluralists	Possession of high degree of resources	Various resources	Society
Mills	Social status and position within institutions	Monopoly over every source of power in society	Society
Bourdieu	Social status and exclusive educational degrees	Transformation of cultural capital into economic capital	Society

Abstract

The term 'elites' refers to those people who, due to their positions, are capable of considerably influencing social developments. Classical elite theories assume an unavoidable opposition of ruling elite and dominated masses; functionalist elite theories assume competing performance and sectoral elites; critical elite theories identify power elites recruited on the basis of social origin. Current elite research discusses most of all the homogeneity of elites, the role they play in the context of an ever more unequal distribution of incomes, and their internationality.

In the current language, 'elite' refers to a small group of people standing out from the overall population due to particular characteristics. The term is used both for top politicians and top managers as well as for outstanding athletes or scientists. Both outstanding achievements and an unusual degree of influence as well as unusual power are considered the essential criteria for considering somebody an elite member. The social sciences apply a somewhat stricter definition. According to the latter's criteria, only those people belong to an elite who are capable of essentially influencing social developments. It is debated, however, which positions must be taken into consideration in this context. This refers first of all to individuals whose social influence is not due to occupying hierarchical power positions but to their personal reputation or prestige. What is also not clear is the limits which must be drawn concerning the rank of the respective position.

Most social scientists include only the top ranks of the classical fields of politics, business, administration, justice, armed forces, media and sciences into their studies. Among them, apart from office bearers at the national level in federally constituted states such as Germany or the United States, there count the top politicians, high ranking public officials or judges of the individual federal states. Mayors are counted only if they govern leading cities of the respective country. Other regional or local elites are usually not taken into consideration. For elite research, top politicians, top managers, high ranking administrative civil servants and judges, top army officers, the publishers, and leading editors of the most important media as well as the top representatives of the big scientific institutions and elite universities form the important social elites.

Individual authors go clearly beyond. This holds, e.g., for the fundamental analyses by Dreitzel (1962) and Keller (1963). For example, Dreitzel states explicitly that not only those occupying top positions, thus immediately contributing to preserving or changing society, must be counted among the elite but also those who, due to their prestige, are capable of acting as role models, thus normatively influencing the behavior of the population (Dreitzel, 1962). Also, Keller includes not only the top ranks of politics, business, sciences, or armed forces into her 'strategic elites,' which she calls 'external elites.' Among elites she also counts outstanding representatives of philosophy and churches as well as famous artists, authors, entertainers, film stars, or athletes, so-called 'internal elites,' who in her opinion are responsible for the formulation of moral standards and for maintaining everyday morality (Keller, 1963). However, for extended empirical elite studies this second group plays hardly any role at all. They deal almost exclusively with the top representatives of the classical sectors. If other fields, such as culture, are represented at all, this does not refer to famous artists, writers, etc., but to cultural managers, i.e., those occupying leading positions of publishing houses and the arts sections of the media.

Accordingly, in modern industrial societies the crucial elites come from the fields of business, politics, administration, and justice. In this respect they are the most influential groups. If the boards or owners of big trusts make decisions on their enterprises' future orientations, if a government decides about austerity measures or reforms of the educational system, if high ranking ministry officials formulate draft bills, or if the judges of federal courts make their verdicts – in all these cases it is a small group of people who makes crucial decisions concerning the life of the broad population. For the elites from other important sectors, such as the media, the armed forces or the sciences, this definition is true only in a limited sense. Indeed also they are capable of influencing social developments, but concerning crucial aspects they depend on the decisions most of all of political and business elites who, after all, decide about available financial means and overall direction. In individual countries however, such as most of all the United States, also the armed forces count among the crucial elites. Concerning the top representatives of trade unions, churches or NGOs, it is debated if they count among the elites. Most studies from Europe do count them, some studies from the United States do not. The reason is mostly that, other than elites from business, politics, administration, justice, the media or the sciences, they actively or passively (in the form of membership fees) depend on support from their members. The less this support, the less power they have. This may reach as far as to being mostly or even completely insignificant. The power of actual elites, on the other hand, is not connected to being actively supported by the population but solely to occupying an office and/or disposition of property in the form of enterprises. It is structurally rooted in the power structure of society. This holds also for the political elite, as is demonstrated by low and constantly declining turnouts and party

memberships which do not at all restrict the scope of action of the political elite.

The crucial questions, when it comes to the analysis of elites, are How do elites recruit themselves, and what about their inner cohesion? In other words, it is about the vertical and horizontal integration of elites. The vertical dimension concerns the connection between elites and population, i.e., most of all the social origin of elites and the thus connected attitudes. Horizontal integration refers to the way in which the individual elites are connected to each other, by way of social origin, educational, and career paths as well as common attitudes and values.

Classical Elite Theories

All of the classical elite theories, those by Mosca (1896), Pareto (1916), and Michels (1911), were formulated at the turn of the nineteenth to the twentieth century. Their development and great impact is due the bourgeosie's widespread fear of the urban masses and the organized working class in those days. In this extent, the urban masses were a historically new phenomenon. They developed only in the second half of the nineteenth century, as a result of comprehensive industrialization and urbanization (Hartmann, 2007). Theoretically, the elite theories were the alternative to Marxism, which dominated the organized working class. The predecessor of the elite theories was Le Bon's very influential psychology of the masses (1895). There, Le Bon states that the masses, most of all due to being driven by their instincts, are incapable of creating cultures but could only destroy them. Cultures could be created only by small, intellectual aristocracies of superior minds. Accordingly, he says, the masses need leaders who guide them by use of force.

The contradiction between small, ruling minorities, and vast majorities who are ruled is also the bottom line of classical elite theories. For them the division into a ruling class or elite – Mosca calls it the ruling class, in Pareto it is the ruling class but also the ruling or governing elite – and a mass which is ruled is the basic principle which is valid for all societies and forms of government. The elite rules due to its superior material and organizational possibilities as well as to its intellectual capabilities and by use of force. In Mosca's and Pareto's opinion, all elites tend toward monopolization and bequeathing their power positions. Thus, there is a constant conflict between these aspirations and the upward aspirations of parts of the masses. Either these upward aspirations are taken into consideration by way of the permanent integration of individual elements of the dominated class, or the ruling class will be overthrown in the course of revolutions. Pareto calls this process the elite cycle. Michels, whose analysis refers basically to political parties, completes Pareto's and Mosca's explanations by stating that all human organizations inevitably tend toward an oligarchy.

The Functionalist Elite Theories

Due to their both topical and (in the case of Michels and Pareto) also personal closeness to Fascism, after 1945 the classical elite theories were deeply discredited. They were replaced by the still today dominating functionalist or pluralist elite theories, from Lasswell and Kaplan (1950) via Dahl (1961), Dreitzel (1962), and Keller (1963) as far as to Field and Higley (1980). Their two core statements are clearly different from the classical elite theories. In their opinion, there is no more ruling class or elite but only individual, competing subelites in the various fields of society. Also, they say, there is no lasting hierarchy of these subelites. Secondly, access to these elites happens primarily via individual performance. The still observed predominance of the upper classes among the elites is said to be due to their better access to education instead of heredity and will step by step disappear with the extension of the educational system.

However, according to the functionalist elite theories, the existence of subelites and access via performance causes a grave problem. The heterogeneity of elites, due to their division into different sectors and their recruitment from different classes, is said to endanger the consensus among the elites. Whereas in traditional societies it was created by way of the existence of a ruling elite and a common social origin, these days it cannot be taken for granted. However, such a consensus on basic values and the way of settling conflicts is said to be indispensable for modern societies. To establish it, as is the opinion of most functionalist elite researchers, the elites must support their positions offensively. Only the elites, they say, are capable of securing the stability of parliamentary democracies. Stability is never, as Field and Higley say, the result of the voluntary and peaceful cooperation of all social actors but always only the result of prudent decision-making by the elites. Thus, the danger does not come from the elites but from too much influence of the masses. Field and Higley support this position particularly harshly, like Lasswell and Kaplan before them, but also almost all other functionalist elite sociologists see things similarly. For example, Keller believes too strong demands for democracy, equality, and elite responsibility to be one of the greatest dangers for democracy in modern societies. After all, all these elite researchers agree that the elites' scope of action must not be restricted by the influence of the broad population.

The Critical Elite Theories

Already at a very early stage, in the 1950s, Mills (1956) criticized the functionalist elite theories. Then most of all Bourdieu (1979, 1989) discussed them critically. Both theoreticians agree that the basic assumptions of the functionalist elite theories are wrong. In their opinion, there are neither subelites of equal rank nor recruitment according to the performance principle. Concerning the former point, still Bourdieu in most of his works even uses the term 'ruling class.' However, in contrast to the classical elite theories he does not equal it with the elite but refers to that of the three great social classes from which those occupying top positions are predominantly recruited. Mills uses the term 'power elite.' This way he wants to make obvious that for him 'class' is an economic concept, but rule is a political one, and also he wants to avoid the risk of underestimating the autonomy of the political elite.

For Mills, the power elite consists of the top representatives of politics, business, and armed forces. In his opinion, these three sectors dominate all other sectors because those decisions as being decisive for the development of society are made by those being at the top of the highly centralized power apparatuses of politics, business, and armed forces. Most influential in this context, he says, are the top managers of the big trusts, whose power nobody can resist in the long run. The interwoveness of the three sectors as well as common interests, together with a mostly identical origin from the upper classes and a mostly common worldview, provide a high degree of stability and cohesion within the power elite. Apart from growing up in the upper classes, he states, also being educated at a country's elite universities and the recruitment criteria and values common among these circles are the reason for social homogeneity.

Concerning the significance of social origin and elite educational institutions, Bourdieu mostly agrees with Mills. This holds also for another crucial point. Also Bourdieu considers the owners of economic capital to play the dominating role within the ruling class, thus calling them the ruling faction of the ruling class. However, in contrast to Mills, he is not interested in the question of who makes the important socially relevant decisions and how they are made but first of all in the reproduction of the ruling class. Most of all, in his more recent publications he even explicitly distances himself from elite theories because, as he says, he is interested in the analysis of power structures and not in analyzing power actors. In his opinion, a class-specific habitus and elite universities are crucial for the reproduction of the ruling class. They make sure that the important power positions can be handed over to the offspring even without being directly bequeathed. By way of the class-specific habitus, he says, an individual's experiences from growing up in a certain family environment are impersonated. It is a system of dispositions determining perception, thought and behavior, and it mediates between an individual's position in the social space and his/her lifestyle. This habitus, he states, decides essentially about the chances of being accepted at one of the elite universities and of acquiring their exclusive academic grades. The latter, on the other hand, are then the precondition for rising to the important power positions. This way the reproduction of the ruling class is secured. In contradiction to its claims, Bourdieu says, the educational system is not characterized by equality of opportunity but by subtle mechanisms of the reproduction of class structures. Thus, access to top positions is indeed not primarily based on individual performance but on the individuals' class-specific habitus.

Bourdieu and Mills do not only share their rejection of the basic theses of functionalist elite theories: In contrast to the latter, as essential explanatory elements they always include the class situations in the respective societies into their analyses. In Bourdieu, this is obvious because it is one, if not even the essential, aspect of his entire work. But also in Mills the class situation plays a crucial role. This becomes obvious most of all when he explains the declining influence of the political elite, in particular of professional politicians, in comparison to business and military elites. In his opinion, two processes are responsible for this: The decline of the traditional middle class of economically rather independent farmers and freelancers in favor of the new, economically dependent, middle class of white-collar workers and the loss of power of the organized working class. The significance of the traditional middle class and (even more) the organized working class, he states, were the basis of the (most of all during the New Deal) unusually big scope of action of the political elite. The mass of the population does not contribute anymore to the political life but is manipulated by the mass media. Thus, for Mills mass society and power elite form an inseparable unity.

Recent Developments in Elite Analysis

In the field of sociology the interest in the topic of elites has clearly grown in the past two decades. Since the turn of the millennium alone there have been quite a number of publications dealing first of all with the analysis of European elites, although in single cases also the elites of non-European countries such as Japan (Colignon and Usui, 2003) and the United States (Domhoff, 2009) are discussed. There exist both compilations of smaller country studies, such as on the political elites of Southern Europe (de Almeida et al., 2002) or the economic elites of East Europe (Lane et al., 2007), and publications which, on the basis of the authors' own empirical surveys, deal with the elites of Germany (Hartmann, 2013), Denmark (Christiansen et al., 2001; Ellersgard et al., 2013), France, and Great Britain (McLean et al., 2006), Norway (Gulbrandsen et al., 2002; Hjellbrekke and Korsnes, 2009) or of all of Europe (Hartmann, 2010). Usually it is about the social profile of elites, i.e., their social recruitment, their educational and career paths and their connections to each other. The social–political attitudes of elites are included into the surveys only in the cases of Germany and Norway (Gulbrandsen et al., 2002; Hartmann, 2013). Theoretically, the functionalist concept of elites is still dominating; the majority of current empirical studies (Colignon and Usui, 2003; Domhoff, 2009; Ellersgard et al., 2013; Hartmann, 2013; Hjellbrekke and Korsnes, 2009; McLean et al., 2006), however, takes a critical attitude following the tradition of Mills and Bourdieu.

The great interest in elites is basically due to two grave social changes: The fall of the Eastern Block and the rapidly growing gap between the poor and the rich in most industrial states. For the first time after the end of World War II, the end of the Eastern Block has raised the urgent question in Europe if and in how far there happens an exchange of traditional elites. The fast growing differences between the poor and the rich raise the question of the role of the elites in this context.

Concerning the development in the countries of the former Eastern Bloc, regarding the elites the situation looks much varied. There are countries where rather soon the old elites were mostly replaced. With the exception of the special case of the GDR, where the old elites were almost completely replaced by people from the old Federal Republic of Germany, this holds most of all for the Baltic states, Poland, Czech, and Hungary. In Poland, Czech, and Hungary this exchange concerns most of all the sectors of politics, administration, justice, armed forces, and media, whereas in the business sector often members of the higher management ranks simply moved one step further, to the top of enterprises. Thus, in this field the elites have only

been partly replaced. In a number of other countries, such as most of all the successor states of former Yugoslavia and Russia, this process started only later and most of all with the political elite. There, the members of the former political elite did not simply leave or join the opposition parties, but after having been replaced quite often they took over top positions in business (Eyal et al., 1998; Lane et al., 2007). In some states, such as Bulgaria, Romania, or White Russia, the exchange of elites has been only very limited or hardly at all.

The rapidly growing differences in income in many industrial countries have resulted in an intensive debate on the question if and in how far the elites, whose scopes of action have clearly been extended due to the massive weakening of trade unions as a result of globalization, are responsible for this development. What is most of all of significance in this context is the question of how far the elites have been closing off from the rest of the population. Current studies pursue this question most of all by asking about the social recruitment and the educational and career paths of elites. Their results can be shortly summarized as follows: In most European countries the social recruitment of elites has become more exclusive, and also regarding their educational and career paths the elites have become more homogeneous. However, in this respect there are great differences in West Europe. On the whole, there exist three basic types of elite formation: firstly France, which knows both institutions of elite education and elite corps of state administration; secondly Great Britain and Spain, who have institutions of elite education or elite corps, respectively; and thirdly the other countries which have neither the former nor the latter (Hartmann, 2010).

In case of the first two types, the elites are more closed off from the population than in the third case. The essential reason is the elite institutions, which are attended by the majority of their members. These institutions do not only provide for social exclusivity, due to their access procedures, but also for a high degree of internal homogeneity due to the time their members have spent together when attending them. The overwhelming majority of the elites in these countries come from the upper or upper middle class, i.e., the upper *c.*4% of the population in the generation of their fathers. Concerning the business elite, about four-fifths come from these classes, with the elites of justice, armed forces, politics, and administration it is between three-fifths and three-quarters. Due to their origin and the time they have spent together at institutions of elite education and/or elite state institutions, these elites achieve an outspokenly high degree of internal homogeneity. In other West European countries, the degree of elite homogeneity is traditionally clearly lower. There exist neither institutions of elite education nor common career paths. Furthermore, the individual subelites are very much different concerning their social origin. On the one hand, there is usually the business elite, whose social recruitment is frequently the most exclusive one; on the other hand, there are most of all the political and/or administrative elites which are the most open ones in this respect (de Almeida et al., 2002; Hartmann, 2010; McLean et al., 2006). However, social origin varies much from country to country. Socially most exclusive are the elites in Germany, and this exclusiveness has partly even been growing in the past decade. In business, their recruitment is as exclusive as it is in the case of the elites in France or Great Britain, in the justice and administrative sectors it is almost as exclusive, with a share of two-thirds of upper or upper middle class children. Also with the political elite, which for half a century was clearly dominated by people from the broad population, social recruitment has clearly changed since the turn of the millennium. These days, about one half of top politicians come from the upper or upper middle class, whereas in the past it was only one-third. Furthermore, changing from elite positions in one sector to those in another sector has become much more frequent. The homogeneity of German elites has thus much increased (Hartmann, 2013). The Scandinavian states form the antipole in Europe. They are the least socially exclusive ones. There, people from the broad population are represented much more frequently than with the other European elites. This holds in particular for those coming from the working class. Almost in every sector elite members from the upper or upper middle class are in the minority. Furthermore, in the past decades the elites have somewhat opened up. However, the appropriate data for the Danish business elite are debated, as becomes obvious by the debate on the result of the Danish elite study by Christiansen et al. (2001) (Ellersgard et al., 2013; Gulbrandsen et al., 2002).

Furthermore, for Norway Gulbrandsen (2008) analyzed in more detail the mutual trust among elites as an essential precondition for elite consensus. He presents four essential results. Firstly, mutual trust is lower than originally assumed by the researchers. Secondly, the subelites mostly trust the elites of comparable sectors, e.g., the military elite has confidence in the elites of justice and police, or the administrative elite has confidence in the political elite. Thirdly, the basic political attitude toward the welfare state plays a crucial role for mutual trust. This is an essential, if not the only, reason why, fourthly, of all elites the business elite has the least confidence in the political elite and why at the same time all other elites have comparatively little confidence in the business elite. In both respects, the latter is an outsider.

On the German business elite there exists a study which, by way of the careers of 6500 engineers, jurists, and economists with a doctoral grade, explains the exclusive social recruitment of this elite and doubts the functionalist thesis of performance-oriented recruitment. It shows that social origin and the thus connected class-specific habitus influence the access to elite positions, not only by way of achieving high educational degrees but quite directly. Even in case of identical preconditions concerning educational features, the probability for those with a doctoral grade coming from the upper class to reach the uppermost floor of a big enterprise is more than double than for their mates from the broad population. If their fathers were board members, their probability is even 17 times as high as for their mates whose fathers were working class (Hartmann, 2002).

These differences in the social recruitment of elites come hand in hand with differences in the distribution of incomes. In this respect, the Scandinavian countries show the least differences, Great Britain and the big continental-European countries the biggest ones. The statistical relation between the distribution of incomes and elite recruitment can be explained if one looks at the relation between the social origin of elites and their social–political convictions and

attitudes. The most recent study on German elites (Hartmann, 2013) has analyzed this connection in more detail.

The attitude of the elites, as is the result, is clearly characterized by their social origin, most of all when it comes to judging on social differences and the reasons for the current financial crisis. Whereas almost three quarters of the population consider the social differences in Germany to be unjust, among the elites only a minority is of this opinion. However, even among their ranks there are considerable differences. Whereas working class children consider social inequalities to be unjust almost two and a half times as those considering them just, among upper class children the relation is almost exactly the opposite. The answers, if it is about important finance- and labor market-political measures, are appropriate. Whereas among the population two-thirds support a rise of the top tax rate, two-thirds of elite members are against it. In this context, again and again they answer according to their social origin. Two and a half time as often as others, elite members with a working class background believe tax increases for high incomes and great fortunes to be important. This difference is basically found with all subelites, if at different levels respectively. Concerning the essential reasons for the financial crisis, the situation is the same. Those elite members as coming from working class families clearly believe the deregulation of the financial markets to be the most important reason, a four-to-one majority of those who grew up in upper class families, on the other hand, believed the national debts to be the most important reason. The majority of working class children identified a responsibility of deregulated markets, upper middle, and upper class children saw a responsibility of the state and, most of all, social benefits. This attitude is found across all sectors. Thus, the connection between the social recruitment of elites and the development of incomes is not only one of statistical data but is explained by the convictions and attitudes of elite members which are influenced by their social origins.

One question elite researchers have increasingly, be dealing with in the past one and a half decade is that of the internationalization or globalization of elites. In this context, for the time being research focusses on business elites because as a result of globalization they are much more internationalized than the other elites which, after all, in their great majority are tied to the institutions of the national state. The question is answered very differently. Some researchers state that in business meanwhile there exists a global elite. They point out that the big multinational enterprises are increasingly interwoven, that networks become more intensive, and that accordingly their boards are ever more international. Among the worldwide business elites, as is their position, transnationalists increasingly replace national networkers. Thus, as, e.g., Carroll (2009) states in his study on the boards of the 500 biggest enterprises in the world, we may rightly so speak of a 'global corporate elite.' Kentor and Jang (2004) in their study on the boards of the Fortune Global 500 argument similarly. Also they come to the result that the emergence of a transnational business community is a matter of fact. However, both Carroll and Kentor and Jang admit (in contrast to some other, less empirically working authors) that for the time being this process is mostly restricted to Europe and North America and only marginally includes the business elites of Asia or South America.

The low degree of internationalization among Asian top managers is demonstrated by Pohlmann (2009) in a study on the CEOs of the biggest enterprises in Germany, the United States, China, Korea, and Japan. Among the CEOs of the 300 biggest enterprises of the three Asian countries there are just four foreigners. From this he draws the conclusion that the thesis of global business elites does not stand the test of empirical evaluation. Also Hartmann's study (2011) on the CEOs of the 100 biggest enterprises in Germany, France, Great Britain, Italy, Spain, the United States, China, and Japan points in this direction. With 9 and 18%, respectively, only in Germany and Great Britain a considerable share of CEOs comes from foreign countries. In other countries, on the other hand, it is just 5% or even nobody at all. As furthermore, two-thirds or even nine-tenths of national CEOs have no foreign experience of more than 6 months, one may not speak of an internationalization of business elites or even of a global elite. The still dominating significance of national career paths and institutions of elite education must be considered the decisive reason for this.

Abstract

Jon Elster has contributed to critiquing and also extensively constructing the standards against which to judge social science explanations, and rational choice theory, extending into institutional designs ensuring that analytical work obeys the injunction of methodological individualism and identified plausible mechanism, which explain outcomes, adding indeterminacies, emotions, and norms to the rational choices actors make under limited conditions. His multidisciplinary work has dissected Marxian theories but investigated an array of societal issues of modern times.

General

Jon Elster (born 22 February 1940, Oslo) is a Norwegian, currently Paris-domiciled social theorist who has contributed to the philosophy of social science; rational choice, game and collective or public choice theories; behavioral economics; institutional design models; the theory of distributive justice; and the history of social thought. He has also been involved with Analytical Marxism, most recently 'analytical sociology' and the critique of rational choice and public choice theory, especially on the grounds that they inadequately capture social realities. His more than 24 books to date (many published by Cambridge University Press) plus many edited volumes have been translated into many (17) languages. In addition, he has written *c*.200 articles. Elster's work has been multidisciplinary, covering the full array of the social sciences and extending into literature and history. He has never felt the need to seriously connect up with the associational life of particular academic disciplines. His work is studded with numerous examples from contemporary life, literature, and history.

Intellectual Trajectory

Both Elster's parents were writers: his mother (Magli Elster) wrote poetry while his father (Torolf Elster) wrote novels and short stories and was a political journalist for much of his career and then CEO of the Norwegian Broadcasting Corporation. His father had university degrees in mathematics, mechanics, and astronomy. The effect of this family situation was constant exposure to rigor and clarity, imagination, creativity and moral integrity together with left politics. His mother's family had lived in Paris where her father was a translator and writer of a Norwegian-French dictionary, so this provided some French ambience. These maternal links with France were reinforced through an exceptionally stimulating French teacher in high school. After his high school degree in 1958 and a summer job, Elster went to Paris for 3 months in order to learn French. At the Pris Alliance Française, there were many foreigners which allowed improvement of his English. He was Vice-President of the French students' Association, and married its President.

Mathematics and literature were early passions and these were supplemented by reading French and philosophy at the University of Oslo. After several years of study there, Elster wanted to study Marx, to establish more solid foundations for his intuitive socialism. But this, in turn, required study of Hegel. So, in 1966 he went to Paris to work with prominent Hegel scholar Jean Hyppolite. However, Hyppolite directed him instead to study with Pere Regnier, Gaston Fessard, and other Hegel scholars in a Jesuit monastery at Chantilly. The resulting dissertation (partway between a Masters and PhD in size) "Prise de conscience dans la Phenomenologie de l'Esprit de Hegel," was defended at the University of Oslo. While Elster found some parts of Hegel inspirational – such as his stunning analysis of the master–slave dialectic – he found most of the texts nearly impenetrable.

However, by 1968 he again wished to go to Paris, to now study Marx more generally and again he was sponsored by Hyppolite (then Director of the Ecole Normale Superieure) to obtain a place as 'pensionnaire etranger' and to supervise a dissertation for a Doctorat d'Etat. However, Hyppolite died so he turned instead to Raymond Aron (Directeur d'Etudes at the Ecole Pratique des Hautes Etudes) to be his supervisor. Elster found Aron's common sense and discussions at his seminar (including the interventions of classmates) were helpful. Outside of these seminars Aron and Elster only met once or twice a year to discuss drafts of dissertation chapters, and this left Elster to lay the foundation for much of his later work. Working backward from Marx meant coming to grips with Marxian economics and then to understand economic theory more generally, and especially its foundations in rational choice theory (RCT). Understanding Marx also required delving into economic history. Luce and Raiffa's *Games and Decisions* was an especially important source. Elster wrote a book in Norwegian (which was then included in his dissertation) on methodological problems of economic history, which led shortly thereafter to an academic post in Oslo. The thesis ('Production et reproduction: Essai sur Marx') was defended in 1972 in front of a jury consisting of Paris intellectual leaders Aron, Raymond Boudon, Jean-Claude Casanova, and Alain Touraine.

From 1971 to 1973, Elster held a University fellowship in Oslo and then taught Sociology for a year at the Universite de Paris VIII (Vincennes) with his work mainly focusing on Leibniz while he taught courses in Mathematical Sociology and Marxism.

In 1975, Elster became associate professor at the University of Oslo, with a joint appointment between the departments of

philosophy and history. Having failed to find a French publisher for his dissertation, he, therefore, ceased working on Marx, and instead drew on his readings in the rational-choice literature and on earlier training in logic to develop his work on rationality and its limitations. *Sour Grapes* (1983b) claims that there is a large class of states that are essentially by-products of action undertaken for other purposes and cannot be brought about intentionally. For example, one cannot achieve spontaneity or forgetfulness, or overcome insomnia, impotence or stuttering, by pure acts of will. Another claim is that there is a large class of preference structures, especially 'adaptive preferences' that depend on the options available to the agents rather than being independent of them, as is assumed in standard economic theory. For example, in the well-known fable the fox found the grapes sour only because he could not get to them. Counteradaptive preferences are the opposite case; e.g., "Forbidden fruit tastes best."

Explaining Technical Change (1983a) focused on explanation in the social sciences, with particular attention to the important topic of technology, which is widely seen as the driver of modern 'progress,' and was further developed in *Nuts and Bolts* (1986f). Having distinguished three main forms of scientific explanation: causal, intentional, and functional, Elster relates these to each of four theories of technical change: neoclassical theories, evolutionary theories, Marxian theories, and Schumpeter's theory. Elster insists on methodological individualism and attacks functionalist explanation.

G.A. Cohen's work on *Karl Marx's Theory of History* (1978) provided the opportunity for a reconsideration of Elster's Marxist work, after he had rested this interest for over a decade. Elster, Cohen, John Roemer, and others founded a small group of 'analytical Marxists' in 1979 that met annually (or biannually), although he bailed out in early 1990s. Its members produced a series of books published by Cambridge University Press, including as its first a wholly revised version of Elster's dissertation, *Making Sense of Marx* (1985). Elster criticized many areas of Marx's writing including his philosophy of history, economic theories, theory of the class struggle, and theory of the state. Nevertheless, Elster retained respect for Marx's normative theories a criticism of capitalist alienation, and Marx's holding out a life of active and communal self-realization as the positive alternative.

Elster then returned to issues of rationality in particular, reacting to a provocative newspaper editorial arguing that in child custody litigation the choice of a custodial parent should not always follow 'the best interest of the child' principle. Elster argued that it might be in the better interests of the child if a simple mechanical rule such as a presumption for maternal custody were to be uniformly followed or, more radically, choosing the custodial parent by the toss of a coin. Thus, emerged 'Solomonic judgements,' later (1989) published as a book with the same title. Following on from Otto Neurath, Elster argued that in many cases where reason is powerless to yield determinate outcomes, the best one can do is to leave the decision to chance.

Around the same time the Swedish Association of Employers asked Elster to write on the Swedish system of collective wage bargaining, which seemed to defy explanation in terms of RCTs of bargaining. Stronger labor unions, despite being able to realize their rational self-interest, which was based in bargaining from strength, choose not to do so because they felt constrained by powerful norms of equality. This drew Elster's attention to the role of norms.

In the mid-1970s, Elster had been visiting professor in the philosophy departments of Berkeley and Stanford a few times, and had made occasional guest appearances at the University of Chicago. He was invited in 1979 to come as a visiting professor to the Political Science Department at the University of Chicago, and received tenure there in 1984. Also, the thrust of his work was changing in this period from philosophy of the social sciences toward social science proper.

A Range of Books Were Produced Over the Following Decade

Ulysses & the Sirens (1984/1979) is composed of studies in a descending sequence from perfect rationality (characterized by an actor's capacity to relate strategically to the future), through imperfect and problematical rationality, to irrationality.

The Multiple Self (1986b) considers whether the self is a unity or as a divided 'multiple self' with the latter conception helping to understand problems of self-deception and weakness of will.

The Cement of Society (1989) addresses the contrast between rationality and norms more systematically, adding many other examples to that on wage bargaining. Elster argues that there are two extreme cases: the high-stakes e.g., norms of revenge, feuding or dueling and the low-stakes norms of e.g., etiquette, dress, speech, and points out that any unified theory of norms would have to include and explain both.

Local justice (starting around 1987 and published in 1992 a,b) was a project arising out of work on lotteries, which was a mechanism that had been used (in some societies but not in others) to allocate a large variety of goods and burdens e.g., admission to medical school or to military service in wartime. The allocative practices Elster studied operate in a very decentralized way, constrained – but far from determined – by central administrations. Elster also found that the actors' perceptions of what constitutes a fair allocation are a major determinant of the allocative system that emerges.

Political Psychology (1990/1993) shows how belief and preference formation in the realm of politics are shaped by social and political institutions.

By the late 1980s, Elster's immediate interests changed dramatically to comparing constitution-making processes (especially those of the late eighteenth century – the Federal Convention in Philadelphia and the Assemblee Constituante in Paris). Also, some 200 years later Communism began to crumble, leading to Quasiconstitutional Round Table Talks between the government and the opposition that place in many Eastern Europe countries, followed by constitutional amendments and, in some of these countries, election of assemblies with the task of writing wholly new democratic constitutions, which would then be significant in shaping political development. Elster reacted to these opportunities by being instrumental in establishing a Center for the Study of Constitutionalism in the Eastern Europe at the University of Chicago Law School, which would gather documentation about constitutional, legal, and political developments in the ex-Communist countries and elaborate a causal analysis of the process of constitution making and of political transitions more generally. Drawing on the work of Jurgen Habermas and Thomas Schelling, Elster claims that constitution-making processes contain elements of impartial arguing as well as of interest-driven bargaining (see Elster, 1993). Many apparently impartial claims are actually based on interest: e.g., when large parties argue for electoral systems based in plurality voting in single member districts, where they do not refer to the fact that this system benefits large parties, but appeal instead to the impartial values of efficiency and governability that are promoted by this procedure. *Deliberative Democracy* (1998) explores decisions by discussion or deliberation as alternatives to more formal voting. *Alchemy of the Mind* (1999) extends Elster's treatment of the role of the emotions in human behavior.

Elster's next set of research projects, in the new Millennium, included:

1. A book on de Tocqueville (arising out of a paper cotaught with Stephen Holmes), which argues that he ought to be read for his sociological, and above all psychological, insights which retain value despite being written some 150 years earlier.
2. The program 'Retroactive justice in New Democracies' addresses the question of how countries that have undergone a transition to democracy handle the transgressions of their prior elites. The scope of the study included the former Communist countries, the post-World War II European war crimes trials and recent transitions to democracy in Argentina, Chile, and other Latin American countries.
3. In 1992, Elster used funding from the Norwegian Research Council to carry out a 5-year study of addictions. Addiction poses, in an acute form, the problem of how voluntary, self-destructive behavior is possible.
4. Revisiting earlier work on the nature of the emotions and their place in the theory of action, Elster read every article on the emotions in the leading journal in the field (*Journal of Personality and Social Psychology*) from 1987 to 1992, and following up references. He found that many of the articles using American college students report the inconclusive results so, instead, in his study introspection, casual observation, novels, philosophy, and social science were drawn on, with the most useful insights coming from the classical French moralists – Montaigne, Pascal, La Rochefoucauld, La Bruyere – together with de Tocqueville and Proust.

Elster transferred to Columbia in 1995 in part because most of his friends and colleagues in Chicago had preceded him to East Coast Universities and he wanted to experience living in New York ('the world's capital'). In turn, his Columbia job allowed him a year off every 3 years, which he spent in Paris. Shortly after going to New York, Elster married a French-American literature scholar, whom he had met in Chicago.

A Further Slew of Studies (Still Ongoing) Has Eventuated

Closing the books (2004) examines how after a change of political system (especially transitions from an autocratic to a democratic, or at least constitutional, regime) a process of transitional justice emerges in which wrongdoers from the previous regime are judged responsible and victims are compensated. In addition to the numerous transitions after 1945 in Western Europe and after 1989 in Eastern Europe, transitional justice arrangements had taken place in classical Greece, the English, and French restorations.

Collective Wisdom (2012) proposes a normative theory of collective decision-making inspired by Jeremy Bentham that in designing democratic institutions the impact of self-interest, passion, prejudice, and bias on the decision-makers should be reduced as much as possible. This rule is prudent given that there is no independently defined good outcome that institutions can be organized to achieve and nor is there any way of reliably selecting good decision-makers.

These Institutional Design considerations are taken up further in *Securities Against Misrule: Juries, Assemblies, Elections* (2013). The obstacles Elster is concerned to guard against include:

- bad sheep in the process (domineering individuals or spoilers);
- ignorance, secrecy, and publicity;
- the effects of strategic behavior by participants;
- cyclical voting outcomes (Arrow paradox);
- dictatorship (institutional arrangements that permit one actor to determine the outcome);
- sensitivity of the collective outcome to the order of the agenda;
- procedural indeterminacy;
- power differentials;
- capture of the process by special interests;
- deadlock through requirements of super majorities; and
- information asymmetries among participants.

Among his recent work has been a trilogy – *Le désintéressement: Traité critique de l'homme économique* – which has consolidated his critique of economic man, mainly through publications flowing from a lecture series given in Paris.

Influences

Overall Elster has not been particularly influenced by extant 'masters' although collegial work with an array of contemporaries has been important. Crucial intellectual seedbeds have been the works of Leibnitz and Marx. But books have been particularly influential include: Robert Duncan Luce and Howard Raiffa's *Games and Decisions*, Thomas Schelling's *Strategy and Conflict*, Joseph Levenson's *Confucian China and its Modern Fate*, Keith Thomas's *Religion and the Decline of Magic*, the first volume of *Das Kapital*, the books by Paul Veyne (e.g., *Bread and Circuses: Historical Sociology and Political Pluralism*), Zinoviev's *The Yawning Heights*, de Tocqueville's several studies, John Rawls's *A Theory of Justice*, and Montaigne's *Essays*. These books had an impact as they offered perspectives on the world. Nonacademic books, of considerable importance, particularly include all the novels of Stendhal and Jane Austen.

Overview of Work

Elster is fluent in Norwegian, English, and French with a reading knowledge of German. Being multilingual, Elster has been sensitive to the potential of different languages for better expressing clear ideas. Moreover, he has lived not only in several urban regions but quite often simultaneously in two, although retaining affection for Oslo as his home town. While these commutes stretched his family life, it also absolved him from participating in academic administrative tasks.

Elster is a member of the American Academy of Arts and Sciences, the Norwegian Academy of Science, and Academia Europaea and is a Corresponding Fellow of the British Academy and a member of Institut Jean Nicod. Prizes and awards have included Prize of the Norwegian Research Council for excellence in research, 1992; Prix Jean Nicod, Paris 1997; John von Neumann award, Budapest University, 2002; Fridtjof Nansen Prize for Excellence in Research, Norwegian Academy of Science 2006. His John Simon Guggenheim Fellowship was awarded for 1989. He has held visiting professorships at many universities and is an Honorary Doctor at many. Elster has facilitated the establishment and (co)directed centers at the University of Chicago (the Center for Ethics, Rationality and Society, and then the Center for the Study of Constitutionalism in Eastern Europe). He has edited several books series, given many named lectures and been on the Editorial boards of a range of journals.

Elster's scholarship could be described as having been broadly very consistent while pursuing a wide array of topics. The direction of this work has not been much planned or foreseen, but he makes attempts to retrospectively rework to conjoin later explorations with earlier material and to rework the earlier material to better fit with emerging conceptualizations. Often opportunities have arisen, which he has pursued while knowing little about the topic, but which has provided opportunities to construct broadly generalized knowledge. He has been assiduous in reaching back to the writings of historical predecessors and then reconstructing their work to elucidate those parts, which work well, while also signposting areas where their work is weak. Some of his work is not systematic, at least during earlier stages of development when there is a tendency to generate a list of elements and then to work through these while more systematic frameworks that might allow more tightly developed schema have yet to be developed.

There is only sparse extended commentary on Elster's work, although his work is cited often. There are two essay collections (Cuypers, 1995; Leschke, 2008); several essay-length reviews, a few autobiographical accounts (Elster, 1995a; n.d.), and various interviews (e.g., with Swedberg, 1990; Guénard and Landemore, 2008) and YouTube appearances.

Philosophy of Social Science

A continuing concern for Elster has been not just to generate social theories but also to reflect on the methodology of social science. Early campaigns denigrated the convoluted looseness of much received theoretical work, especially from various European theorists. However, Elster has also been concerned with the overly common resort to functionalist explaining, especially among US theorists. More generally, he has argued that useless theories create waste and harm – deflecting from the hard work necessary to create useful theories and at worst providing wrong understandings. He sees much of social science as falling into either hard or soft obscurantism: making unrealistic assumptions and relying on very limited research designs on the one hand and falling back onto merely descriptive work on the other.

He believes (and offers this as an explanatory account) that there is a deep-seated human need to perceive meaning and order in the universe, and an equally deep-seated aversion to admitting the existence of chance and accident, sound and fury. Ways in which to satisfy this need for order, shared too by social scientists, include: blaming the victim (to reduce any appearance of injustice), finding conspiracies, appealing to unconscious intentions, transforming into the goal of behavior what can only be a by-product of behavior – and appealing to functional explanations.

Elster regards the usual assumption that the goal of social science is to produce general, lawlike theories, that can yield not only explanations after the fact but also predictions before the fact, to be too ambitious since individuals and societies are just too complicated. However, social science does not need to fall back on being confined to narratives or descriptions. An intermediate strategy for the social sciences focuses on mechanisms: "causal patterns of a simple, general kind that occur in many different situations under unknown triggering conditions or with indeterminate consequences. Ex post, they can illuminate and explain many forms of behavior but they have little predictive power, since we cannot tell ex ante when one will be triggered" (Elster, 2007a: p. 36). There are two general kinds of mechanism: type A are triggered under unknown conditions, whereas by contrast, type-B mechanisms have indeterminate consequences. In a situation of type A, at the beginning of the causal sequence, one or other causal chain is triggered, but we do not know which one. For instance, the prey detects the predator and sometimes this leads to escape, but sometimes the prey ignores the predator. However, in a type-B situation, two (or more) chains are triggered with an indeterminate overall result (net effect) at the end of the evolving causal

sequence. For example, swimming training seems to activate two causal chains so that the net effect of training on risk is often indeterminate: in one, skill tends to depress the risk of misdemeanor; in the other, confidence tends to increase it. Sometimes, confidence in swimming skill increases more rapidly than the skill itself, although the trajectory can be the other way round.

Elster has also upheld the principle of 'methodological individualism' or the principle of 'the need for micro-foundations.' Since only actors can create social outcomes, Elster has resolutely clung to models, which are at base concerning individual activities.

Theoretical Overview

The conceptual architecture of Elster's work has been an extended and grounded version of RCT, in which he has added conceptual elements outside of the traditional framework (especially emotions and norms) but has also explicitly identified limitations of this approach. He sees RCT models as far too abstract and limited, needing to be limited by more realistic pictures. By ignoring the calculative burdens of actors in implementing fully rational actions, RCT theorists produce a science fiction.

Nevertheless, rationality is seen as a basic human conception, although always culturally specific in detail. So, a guiding hypothesis should always be to assume rationality as a first step in understanding what is happening in a situation. Rationality, emotions, and social norms are three main motivations, which can account for most of human behavior. They should be built into explanations, and be considered in that order. Social norms can override rationality, and emotions may override both. For example, when I take revenge, is it because I want to build up a reputation for vindictiveness, because I live in a society with strong norms of revenge, or because I lash out in passion without pausing to think about the consequences? When I help my neighbor, is it because I expect him to reciprocate (instrumental rationality), because it is expected by third parties (social norms) or out of spontaneous empathy (passion)?

The standard model of rational choice relates the four elements: actions (or action tendency), beliefs, desires (or preferences), and information. These relationships can be seen as either explanatory or optimizing. The rational actor optimizes by choosing the action that best realizes his/her preferences, given beliefs about what the options are and about the consequences of choosing one or the other of them. These beliefs are, in turn, inferred from the available evidence by the procedures that are most likely (in the long run, and on average) – to yield true beliefs. On the standard model belief formation is prior to preferences and prior to belief and optimal evidence is gathered (in relation to the preferences and to the expected costs/benefits of gathering more information). There is a feedback loop focused on information that reflects that expected benefits may be modified by the ongoing results of the search process. To these links, Elster adds emotions, of which – he argues – there are some two dozen, which can be well-established. Beliefs can generate emotions, which in turn have consequences for behavior.

There are wider structural limitations that effect behaviors. Some outcomes are indeterminist, there is also irrationality and uncertainty is widespread (i.e., you cannot give a probability for different outcomes). Moreover, some interventions are 'Brute': e.g., disasters. In particular, it is difficult to know numbers and preferences of future generations.

Over the last two or so decades, Elster has also explored similar issues at a more collective (or collective action) level, although he has yet to tie this material together or to relate it to his more individual-level conceptions. The vocabulary used in posing these issues is usually that of 'institutional design.' This is an alternative to the less action-orientated functionalist approach in that the organizational principles are entirely explicit and forward-looking, whereas in functionalism they are implicit and concerned with consequences. Institutional design principles provide the context of individual's situated actions and decisions and the key design idea is to remove obstacles to good decisions. Elster's work has explored three distinct areas: collective bargaining, scarce goods allocation, and finally retributive justice (including issues arising with political transitions).

Elster has not been able to satisfactorily develop his ideas on distributive justice, because of the difficulty of issues than need to be faced. This is in contrast to the idea of rationality, which is relatively unambiguous albeit fenced around with paradoxes and conundrums since in almost all situations almost everybody will agree on what it is rational to do, subject to the problem of indeterminacy. The notion of justice is far more complex since although there is widespread (but not universal) agreement on the importance of distributive principles such as need, rights, efficiency and equality, but ideas about the tradeoffs among these values are very vague. It is also hard to articulate ideas about how the good(s) are to be distributed according to these principles.

In sum, Elster might be labeled (although labels are not important to him) an 'Analytical realist' who sits in the middle of the interplay between the messiness of social reality and the abstract models necessary to explain it, between endeavoring to understand individual decision-making and the institutional contexts shaping this, and between the social science tasks of explanation and the wider tasks of bringing normative assessments to bear.

Effects

Elster's contributions to social science are spread across a wide range, which has given him an equally widespread audience but perhaps has meant that the cumulative effect has not been as great in any of the disciplines covered. Moreover, Elster has made little attempt to link his work with existing conceptual apparatuses of academic disciplines. Writing on Marx during periods when this was a heated topic was not always well-received. In his review essay, Daniel Little wrote a view with which other commentators would undoubtedly concur:

> Elster has made important contributions to several fields. The breadth and depth of his writings are striking in a time of high specialization; he is read and discussed by political scientists,

economists and philosophers. His work is difficult to summarize in a slogan, but it is generally informed by a broad and deep acquaintance with relevant literature in economics, political science, history, philosophy, and psychology.

1992

Conclusion

Elster's intellectual development has both partly negative and largely constructive trajectories. More negatively, his successive disillusionments have included concern over the lack of clarity and soundness of reasoning of many social theorists, including Marx and his predecessors, and then a more generalized loss of belief in the predictive power of the social sciences in general, and that of RCT, more specifically. However, Elster has very considerably extended the microfoundations of RCT by indicating the ways in which emotions and social norms supplement rationality and how individual decision-making is contextualized within institutions whose specific design features have particular consequences. Rather than searching for lawlike theory, Elster has sought mechanism-based explanations and has identified and exposed the workings of a number of these: 'reculer pour mieux sauter,' self-binding, states that are essentially by-products, adaptive preferences, the view of weakness of will as an intrapersonal collective action problem, the tendency for reason to go beyond its natural limits and degenerate into hyperrationality, the civilizing force of hypocrisy, and others. In building up the known repertoire of mechanisms, Elster has often acknowledged earlier theorists and his role has often been to collate a larger range of applications of these mechanisms and then to make explicit pertinent conceptual distinctions. Moreover, while eschewing social commentary and critique his work has often held out implications of considerable policy relevance. But all this is still a work in progress.

Embodied Social Cognition

Caterina Suitner, University of Padova, Padova, Italy
Mauro Giacomantonio, University of Rome 'Sapienza,' Rome, Italy

Abstract

Embodied social cognition refers to the relation between bodily states and higher cognitive processes regulating social behavior. It may operate bottom-up (with sensory-motor system affecting cognition) or top-down (with higher cognitive processing affecting motor responses and bodily feelings). After providing specific examples for both types of embodiment, the main theoretical approaches are presented, together with moderator variables that facilitate or constrain embodied social cognition.

Definition

Research examining the relationship between bodily states and higher cognitive processes that regulate our social behavior (such as making decisions or understanding the intentions of others) can be included under the umbrella of embodied social cognition.

The main goal and principal strength of this research domain and of the related embodied theory of social cognition resides in the attempt to integrate and link different aspects and levels of human experience, from perception to social processes, from motor system to knowledge organization (for a recent overview on the topic see Meier et al., 2012).

The embodied cognition approach stresses the situated nature of cognitive processes, which are influenced by bodily states, by the physical properties of the target object, and by the physical environment in which they are carried out, even when such features are not directly linked to the task. To cite an example that has frequently been interpreted as evidence of embodied cognition, we are more likely to evaluate a humorous target stimulus as funny when we hold a pen horizontally with our teeth (therefore activating the muscles typically involved in smiling) compared to when we block our facial muscles by holding a pen with our lips. What makes this finding interesting is the fact that there is no intrinsic logical reason why facial muscle activity should make visually presented stimuli any more enjoyable.

The idea that bodily states or actions contribute to cognitive processing has received growing interest in social cognition, especially in recent years. As a consequence, cognitive processes that are crucial for social relations (ranging from attitude formation to person perception, up to the bodily grounding of social stereotypes) have been increasingly investigated in relation to the motor system. In doing so, social scientists have primarily focused on two complementary processes, namely (1) the environmental and bodily influences on social cognitive processes (from body to mind) and (2) the embodied display of grounded social cognition (from mind to body).

The first line of research deals with the role of environmental features and congruent bodily states on overtly unrelated higher cognitive tasks and may be referred to as bottom-up embodiment. A multitude of research has provided evidence for the situated nature of cognition by showing that sensory/motor inputs are included in, and exert a direct influence on, the information process. The most important characteristic of this type of studies is that the relation between the bodily state and the higher cognitive process is not directly relevant for the task, as illustrated by the above shift in evaluation of humorous stimuli as a function of facial muscle activity.

The second line of studies takes into consideration the effects of higher order cognitive process on bodily states. This line of studies can be classified as top-down embodiment, in the sense that the body is 'used' by cognition to perform its tasks. According to Barsalou (1999), this type of embodied phenomenon can be explained by a simulation mechanism, namely the activation of a relevant motor modality. For other scholars this is simply a motor resonance of the activation of a semantic network. For instance, while smiling we activate the concept of enjoyment and this semantic activation is responsible for the pen in the mouth effect previously mentioned (see Section Theoretical Perspective).

In the following section, we will review empirical research pertaining to embodiment and its social implications by summarizing few illustrative examples of recent relevant work. We will first examine studies in which sensory-motor system affects cognition, with sensory-motor system being all the sensory processes involved in perception (e.g., seeing, smelling, tasting) as well as motor behavior (e.g., flexing an arm, running). Subsequently, the influence of higher cognitive processing on motor responses and bodily feelings will be considered. Together the findings reported below suggest that social cognition is deeply grounded in the environment in which it takes place, and that social processes and bodily states are linked closely and in a bidirectional fashion. We will then discuss different theoretical perspectives that have been advanced to explain embodied phenomena and the boundary conditions of embodiment.

From Body to Mind: How Sensory-Motor Activation Relates to Higher Cognitive Processes

One of the primary concerns of research in the embodiment tradition has been to demonstrate that environmental features and congruent bodily states contribute to logically unrelated higher cognitive functioning. In other words, individuals use

information embedded in the environment or in their own body to make judgments and evaluations concerning a wide array of domains, even when such information is not directly enlightening about the target to be evaluated. Obviously, as we will see later, this process also applies to and has important implications for social phenomena.

What are the sources of information individuals rely on when forming embodied judgments? As specified by the term embodiment, any bodily state of the person who is performing an evaluative process may in principle influence his or her cognitive processes. Thus, whether the body is leaning to left or right or whether an arm is flexing or extending might be elements capable to affect unrelated judgments, such as political opinions or liking of different social groups. In this case, the motor system of the cognizer is responsible for embodied phenomena in a strict sense. A different, yet related source resides in the physical features characterizing the context in which the cognitive process is taking place, such as – for example – the smell or the temperature of a room. These perceptive characteristics may also pertain to objects that are present in the environment (e.g., a cup, or a clipboard) or even a specific feature of the target itself (e.g., size or brightness). For instance, the height of a person may affect the power we ascribe to him or her. This perceptual source of information is not directly connected to bodily states as compared to the example above. Nevertheless, contextual characteristics might affect bodily feelings and perceptions, thereby being indirectly responsible for embodied phenomena. In this second case, the body functions is a means through which environmental variables affect apparently unrelated higher order cognitive processes. In the following section, we will review relevant work according to the type of source outlined above.

Body as Source

Robust empirical evidence supports the idea that body movements or states (postures) influence social judgments, perceptions, and relationships. The work of Chandler and Schwarz (2009) constitutes a paradigmatic example of this line of research. The authors wanted to test whether hand movements could affect judgments concerning a target person. By means of a cover story concerning the effect of motor activation on cognitive activities, participants were asked to extend either their middle or index finger while reading about a target person described as ambiguously hostile. As hypothesized, the target was seen as more hostile when the description was read while the middle, rather than index finger, was extended. Likewise, a subsequent study showed that a more favorable impression was created when thumb rather than index finger was extended. Therefore, different finger movements affected impression formation of an ambiguous person. Interestingly, the association of the finger movement with a positive or hostile impression is entirely arbitrary and culturally dependent, thus indicating that also bodily states, actions or feelings that are not *hardwired* and connected with evolutionary needs (e.g., cold, carrying a heavy weight, extending vs. flexing an arm) can affect higher order cognition. In other words, also actions and bodily states that we arbitrarily associate with a specific meaning (i.e., extending the middle finger to communicate contempt) and that vary across time, location, and culture can shape our reasoning and social judgments.

The role played by bodily influences on impression formation is not confined to the positive vs. negative dimension, as illustrated by the fact that stereotypes can be promoted by specific information rooted in the body. More specifically, Mussweiler (2006) reasoned that stereotypic movements may trigger the corresponding stereotype, which, in turn, is used to judge a target verbally described with information that is unrelated to body weight. Consistently with the reasoning, the author made participants move similarly to overweight people. This goal was accomplished by asking participants to wear a life west and weights around ankles and wrists and to engage in a series of movements. In a second allegedly unrelated task, a target was judged using both stereotypic (e.g., friendly, unhealthy, lazy) and nonstereotypical dimensions (e.g., musical, creative, forgetful) concerning overweight individuals. Results showed that ratings were more stereotypical when participants' movements were hampered by the vest and the weights.

Besides shifting stereotypic impressions of ambiguously described others, can bodily feedback also affect relatively stable and frequently used schemata? According to Schubert and Koole (2009), it is possible that certain bodily states can influence one's own social self-concept. By signaling the intention or proneness to undertake a certain kind of action, bodily states favor a variation of the self-concept in line with the nature of the action to be taken. Specifically, if a person performs a motor action (such as making a fist), which signals readiness to use physical force against someone else, people should personally experience an increased sense of power. Consistently, the authors found that individuals making a fist rated themselves as more powerful and assertive than participants in a control group both on implicit and explicit measures. Interestingly, these findings emerged only for male participants. A possible explanation is that males more than females associate physical force to power over others; as a consequence, only males' power concept was affected by gestures strictly associated with the use of force. Together, the above examples demonstrate that motor actions or states affect not only how we perceive others, but also personal self-construal.

Contextual Characteristics as Source

In the previous paragraph, judgments relied on the body as source of information. What changed between conditions was mainly a position, a gesture or a movement performed by participants with their own motor system. Conceptually similar findings have been obtained with sources of information that are external to the body, thereby involving the sensory system. As we mentioned above, it is possible to distinguish at least three instances of contextual sources of information that trigger embodied processes.

The first contextual source resides in the general characteristics of the surrounding environment. Thus, the extent to which a room is chaotic or clean might be relevant in determining how we judge the behavior of a person that is not even present in the room or the proclivity to socialize and trust others. Ijzerman and Semin (2009), for example, building on the idea that the abstract concept of social closeness is based on the concrete experience entailing warm sensations, such as the hug, found that the warmth of a room can influence the

perception of social relationships. More specifically, participants in one study were placed in a warm (22–24 °C) or cold room (16–18 °C). Subsequently, relational focus of participants was measured in different ways. Results showed that those in the warm room, as compared to those in the cold room, expressed a stronger relational concern.

The second sensory source of information pertains to the physical features of the object with which the individual is interacting. Surprisingly, physical characteristics of objects we encounter in our everyday activities can shape the way we evaluate unrelated individuals. A study supporting this claim was conducted by Ackerman et al. (2010). The authors asked participants to solve a simple puzzle whose pieces were, or were not, covered with rough sandpaper. Subsequently, an ambiguous social interaction between two strangers was evaluated. As a consequence of this subtle manipulation, participants in the 'rough' conditions evaluated the interaction as less friendly than those in the 'smooth' condition. In a related study, a different object and a different physical characteristic were examined, further reinforcing the idea that embodiment can stem from the artifacts we handle in a mindless way. Ackerman and colleagues tested whether the weight of a clipboard would affect the perceived importance of the social issues presented on that clipboard. It was found that a heavy clipboard (about 1.5 kg) increased respondent's willingness to spend government funding on a variety of social issues as compared to a light clipboard (less than 1/2 kg).

Finally, an unrelated physical feature of the evaluation target may be the source of the information used for the evaluation, as shown in a study by Meier et al. (2004) in which participants had to categorize words (*kiss*, *justice*, *danger*, etc.) as either positive or negative. People found it easier to identify good concepts (e.g., *justice*) as positive when presented in bright (vs. dark) colors, and vice versa for negative concepts (e.g., *danger*), suggesting that responses are facilitated when there is a match between the valence of the concept and the brightness of the stimulus word. The authors explained this effect by noting that, in Western cultures, darkness is metaphorically associated with evil and death, whereas light is associated with good.

Together, the empirical evidence reviewed so far supports the situated nature of cognition. Sensory/motor inputs originating from the body or from the situation are included in the information processing and have a direct influence on it. What is important in this specific line of inquiry is that there is no logical relation between the bodily state and the task. For instance, the height of a target is obviously a key feature to estimate the target's weight, and its influence would not provide any meaningful insight in the understanding of embodied cognition. Differently, the fact that height is a critical factor for estimating an apparently irrelevant characteristic of the target such as social power is taken as evidence for the situated nature of cognition.

From Mind to Body: Higher Cognitive Processes Automatically Activate Motor Responses

In the previous section, we reviewed research examining how context and body affect higher order cognition. This path is particularly important, especially in social life, because individuals generally make decisions and take actions in a situated way that is in a specific context filled with social and perceptual stimuli that affect, in an indirect and surprising fashion, the way they think and judge others.

However, the research reviewed above does not speak to whether this perceptual conceptual path can be reversed. In other words, can the content of our higher cognitive processes affect the way we feel and perceived the environment or even our bodily states (such as our body temperature)? A great deal of research indicates that often our postures or our bodily feelings are a consequence of how we reason and think.

Several examples can be driven from the literature of nonverbal communication, which widely shows that the posture, bodily movements and facial expressions, reveals the psychological state of the person, such as his or her emotions. For example, happiness is associated with the upright position and – of course – with a smiley face. Similar results can be obtained when a feeling is made salient. For example, Zhong and Liljenquist (2006) asked participants to recall unethical (vs. ethical) episodes of their life. When unethical episodes were recalled that presumably threatened the participants' sense of moral purity, they felt the urge for cleansing. This was translated into increased preference for cleansing products over other products and increased likelihood to accept an antiseptic wipe rather than a pen as a free gift.

Previously, we discussed how sensorimotor experience of warmth can shape unrelated social judgments. Importantly, this connection can work in the opposite direction and social experiences can shape our body feelings or perceptions of the surrounding context. The recall of a situation in which a person was socially excluded led participants to perceive a room temperature about 3 °C colder than after recalling a situation in which they were socially included (Zhong and Leonardelli, 2008). In a related fashion, DeWall and Baumeister (2006) drew a parallel between the pain related to social exclusion and to physical injury. The authors argued that, as a consequence of social exclusion, individuals should be less responsive to physical pain. Indeed, in order to cope with exclusion, the capacity of the body pain system to detect both emotional and physical pain is altered and pain thresholds are raised. Empirical tests fully supported this reasoning. In one experiment, for example, a bogus feedback on a personality questionnaire indicating that participants were likely to be alone in their future life increased physical pain tolerance and pain threshold.

Although the mind to body link is well established, more research is needed to fully understand the underlying processes. Recently, some theoretical and empirical efforts have been made in this direction. Neuroscience research, for example, has shown that the mere act of reading words expressing physical actions such as *lick* or *kick* activated neurons of the motor cortex that are also activated when the target action is actually performed (Hauk et al., 2004).

The Theoretical Perspective

So far we have presented embodied social cognition as a line of research that empirically investigates social cognition in relation to the motor system. The practical implications of

these findings are evident. For example, understanding how embodiment works offers practical indications on how to promote specific cognitive outcomes by altering the environmental context. For instance, varying the weight of an object may be a subtle strategy for increasing the perceived importance of such object and changing the room temperature may be a tool for facilitating conflict resolution. All the findings presented above can be easily used for persuasive purposes in numerous applied contexts.

Whereas the practical importance of this line of research is generally accepted, there is considerable debate about the theoretical underpinnings of such effects. Embodied theories are often juxtaposed to the so-called disembodied theories, according to which the motor system is activated as a byproduct of the activation of a superordinate system (often equated to the semantic network). According to this view, the activation of the motor system is simply a side effect of the semantic activation of related concepts. Among the theories that explicitly hypothesize a strong relation between the motor system and higher cognitive processes, we can cite *in primis* the broad theory of Grounded Cognition (see below for a brief description) and the Ecological Approach (Gibson, 1979) according to which environmental or physical features (such as the position of the handle of a target object) affect the elaboration process of the target stimuli even if these features are not directly relevant to the task at hand. For example, if the picture of a cup is oriented with the handle on the right (rather than on the left) side of the visual field, participants more quickly recognize it when they respond with their right hand, showing a facilitating effect of the spatial features of the stimulus. This has been interpreted as functional to action planning, in this case to grasping that is facilitated when handle and hand are on the same side (Phillips and Ward, 2002). Affordances refers to the relation between the environment and the person acting in it, and specifically to the environmental or object characteristics that are relevant for the interaction (e.g., the handle is an affordance offered to people by a cup). Such characteristics of the object are therefore included even in tasks (such as the categorization of the color of the cup) that do not require an action in which the affordance (in the example the handle) is relevant (Phillips and Ward, 2002). Another frequently cited approach is Conceptual Metaphor Theory (Lakoff and Johnson, 1999), according to which the use of conceptual metaphors based on physical features (e.g., the vertical metaphor to indicate power, see 'upper status') creates a motor resonance that explains the relation between cognition and bodily states. One way to reconcile the theoretical definitions of embodiment is to distinguish between a hard and a soft version of the embodied cognition perspective.

Soft vs Hard Approach of the Embodiment

The *hard view* on embodied cognition is primarily based on Barsalou's (1999) Grounded Cognition Theory, according to which any cognitive process or representation is deeply embedded in a specific bodily modality. The grounded cognition hypothesis suggests that sensory-motor and intellectual activities do not represent two distinct systems, rather they are thought to be the constituents of embodied cognition. Put simply, cognition *is* a sensory-/motor-based process. According to this view, the architecture of the human mind is made of direct connections among modality-specific representations. For example, the perception of size is the modality that is connected to the concept of social power, therefore observing a tall person directly promotes the attribution of power. In off-line situations, the bodily state precedes the task, and a simulation mechanism reenacts relevant physical modalities to fulfill thinking. For example, when we feel powerful, we activate the sensory state that is relevant to the concept of power, namely straightening our back and thereby increasing our body size. In the example, the self-evaluation consists in the motor simulation. Accordingly, we activate our own mirror and motor system when understanding actions performed by another person. The mirror neuron system provides a correspondence in the neural activation during the actual execution of an action and the observation of other person's action and this system is supposed to allow several key social processes, such as understanding other persons' intentions and behaviors, as well as self-awareness and learning through imitation. According to the hard view, the sensory-motor system is involved in any type of information processing. This perspective also implies that cognition is always grounded in the body and that the motor system is automatically implied during any cognitive activity. The *chain of causality* is bottom-up, from body to cognition. The hard view has been criticized by scholars arguing that the empirical findings that have been interpreted as evidence for embodiment can be easily interpreted from a disembodied theoretical perspective.

Whereas the hard version implies the lack of an a-modal system (being it semantic, symbolic, or statistical) that orchestrates such representations, the *soft view* grants the necessity of an a-modal superordinate system that structures and organizes modal and embodied representations. The role of bodily states is therefore a crucial aspect of cognition, but cognition is not equated to the motor/sensory system. Thus, whereas the hard view conceives cognitive processes entirely as a product of bodily states and of their simulations, the softer approach views cognition as bidirectionally related to bodily states, but does not embrace the idea that cognition is totally and exclusively rooted in the body. Rather motor and sensory states can be seen as instantiations of cognition. In this softer view of embodiment, cognition is made of symbolic, abstract and a-modal representations fed by bodily modalities that represent at the same time (1) the ground in which cognition is embedded and (2) the means through which cognition expresses the output of its processes. We perceive through our bodies, we act through our bodies, we rely on perceptions of our bodily states. Both at input and output level in encoding and decoding processes, the modalities of our body constrain the cognitive processes. This soft approach allows for both modality-specific representations of concepts and a superordinate system managing such modal representations.

Moderators

After an initial emphasis on demonstrating the existence of embodied phenomena, research on embodied cognition is now turning to the analysis of related underlying processes. As

in many areas of psychological research, this attention on processes is reflected not only in direct assessment of mediating variables but also in the analysis of moderators that define the boundary conditions under which embodied phenomena are likely to emerge. Although currently in an early stage of development, this newly developing line of research deserves attention for two main reasons. First, it represents a theoretical perspective that is rapidly gaining ground, namely that embodied cognition is a process that is activated under specific conditions and that can reach different degrees of activation depending on the situation and on needs. The second reason is that such preliminary findings are likely to have a strong impact in the understanding of embodied cognition. We will briefly describe some of the major moderators of embodiment that have been individuated at this stage.

Familiarity

Familiarity has been proposed as a moderator in the evaluation of importance based on weight. Chandler et al. (2012) hypothesize that the embodied process requires the presence of prior knowledge that serves as an anchor. For instance, greater weight of a book will make a known book appear more important, but weight will not be influential when the book is unknown. Similarly, the weight of coins will affect the estimation of currency value, but only to the extent that participants are already familiar with the currency.

Consistency

Another moderator is the consistency between the motor activity on one side and the information to be processed or a primed psychological state on the other. For example, arm flexion (extension) movements facilitate the processing of and memory for positive (vs. negative) information, because flexing is an approach behavior that is more congruent with positive elements, in contrast with the complementary association between avoidance and negative elements (Forster and Strack, 1998). Similarly, the memory of presented information is improved when the affective valence of the motor activity (e.g., extending vs. flexing the arm, or smiling vs. frowning) matches the affect of a primed concepts (e.g., positive vs. negative words, Centerbar et al., 2008). This match supports the idea that online motor activity interacts with previous knowledge and suggests that it is subject to selection biases, similarly to any other type of information.

Modality match

In addition, embodied phenomena are stronger when the modality of the action involved during the cognitive process matches the modality through which the embodied concept has been acquired. Testing the role of physical washing in cleaning the guilt experienced after an immoral act, Lee and Schwarz (2010) made their participants lie using their mouth (lying via voice mail) or using their hands (lying via e-mail) and asked participants to rate the desirability of a mouthwash and of a hand sanitizer. After lying by e-mail participants rated hand sanitizer more positively, but after lying using their voice participants rated the mouthwasher as more desirable. Participants seemed to search for a specific behavior able to clean their immoral act, confirming that the bodily modality of experience is not a-modal or a-specific.

Construal Level

A final, somewhat controversial moderator is construal level. Construal level depends on the psychological distance of the object or events such that distal objects are represented with higher level of construal. Higher level of construals correspond to abstract, decontextualized, and schematic representations of objects or events. In contrast, lower level of construals correspond to concrete, contextualized and detailed representations. According to Maglio and Trope (2012), embodied phenomena are more likely to occur at low levels of construal, namely when people elaborate information attending to peculiar and local characteristics. Carrying a heavy backpack affected visual length estimation only when participants were primed to attend to local characteristics. To the contrary, Suitner and Giacomantonio (2012) suggest that embodiment is more likely to emerge under low construal only when the embodied phenomenon is bodily driven (such as the body to mind type of embodiment discussed earlier). The authors indeed investigated a top-down (or mind to body) phenomenon, i.e., the Spatial Agency Bias,which is a cognitive horizontal asymmetry that is related to writing direction. Left-to-right readers usually prefer, visualize, and represent left-to-right acting targets. The agency of a target can be physically defined (e.g., moving targets) or socially defined (e.g., high status targets). The Spatial Agency Bias was stronger under high construal level, namely when the information is processed in a global fashion, without attending to contextual details. Specifically, when primed with high construal level, participants drawings were more aligned to their habitual writing direction, namely they placed more often the agentic target spatially before the receiving target in representations of dyadic interactions. Additional research is needed to clarify the role of this moderator.

Together, these new lines of research suggest that embodied cognition is less general and pervasive than originally thought. Rather than being an undifferentiated, universal mechanism, embodied cognition seems to be constrained by a number of variables including prior learning history, coherence of modality, and the perceiver's current mind-set.

Embodiment and Culture

Gabe Ignatow, University of North Texas, Denton, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Influenced by developments in cognitive neuroscience and by internal disciplinary debates, social scientists are rethinking what culture is, how it is learned, and how it ought to be studied. Rather than imagining culture as systems of abstract symbols contained within the minds of individuals, scholars are increasingly analyzing culture in terms of embodied practices (including linguistic and cognitive practices) learned as techniques and ingrained as habits. Some of the major theoretical and methodological developments that have attended this conceptual shift are reviewed here.

Introduction

Research programs in the social and behavioral sciences are often categorized in terms of several key dimensions. These include the *scale of analysis* of research, from microlevel studies of the mind and brain to macrolevel research on global economic systems and social trends. A second dimension is *universalism versus particularism*: while some (*nomothetic*) research seeks to identify universal principles and mechanisms underlying behavior, more culturally oriented and *idiographic* research explores the heterogeneity of human beliefs and practices over historical time and across social groups. Other categorizations include *critical versus applied* research, and research employing *qualitative versus quantitative* methods. Another, somewhat less frequently referenced dimension useful for categorizing social research programs is their *degree of embodiment*. This refers to the extent to which social and behavioral research takes into account bodily dimensions of, and influences on, social behavior, or else treats the body, and research on the body (generally from cognitive neuroscience, biology, and psychology) as irrelevant or orthogonal to social research. The embodiment dimension might be assumed to be equivalent to the universalism–particularism dimension, but this is not the case, as there has been a substantial amount of both nomothetic and more culturally oriented and idiographic social science research that takes into account bodily phenomena. In this article, I review recent developments in the latter of these categories of research: studies of cultural phenomena such as language, symbols, rituals, ideologies, and institutions that take into account, in one way or another, bodily processes.

Social scientists are divided in terms of their interest in results from fields such as cognitive neuroscience, biology, and psychology. Many sociologists and anthropologists take their cue from the anthropologist Clifford Geertz in treating culture as an emergent macroorder social fact irreducible to psychological and biological processes (Geertz, 1973: pp. 92–93). According to Geertz, though humans' capacity for culture is a product of natural selection, culture is so extraordinarily malleable and adaptive that it is effectively functionally autonomous from biological processes. For Geertz culture is a self-contained universe of symbols and social meanings, and as such contemporary research from biology, neuroscience, cognitive science, and psychology is assumed to be of little relevance to cultural analysis. Research from these fields might help social scientists to understand something about the raw materials from which cultures are constructed, but Geertz's position implies that these fields cannot produce insights into the group- and individual-level processes that generate, reproduce, and transform culture's varied forms.

Today, the growing ranks of social scientists who are expropriating insights from cognitive neuroscience, biology, and psychology (e.g., Cerulo, 2002) have put Geertzian arguments for the strict separation of cultural social science from biology and cognitive neuroscience on the defensive. Within sociology in particular, a touchstone for post-Geertzian cultural analysts (who are empowered by sociology's disciplinary position as an 'irremediably interstitial' field (Abbott, 2001: p. 6) that regularly exchanges ideas with many other fields of inquiry) is Pierre Bourdieu's treatment of the ancient idea of *habitus* (Wacquant, 2004; Lizardo, 2013). A shorthand term for these scholars, whose work has intellectual roots in the French tradition of psychologically informed sociology of Durkheim, Mauss, and Bourdieu, is 'practice theorists.'

'Strong' practice theory in sociology (Lizardo and Strand, 2010) conceptualizes culture in terms of socially learned, intertwined bodily, cognitive, and linguistic *skills* rather than in terms of units or systems of abstract knowledge (Bloch, 1986). More precisely, such 'strong' practice theorists are part of a 'third phase' of Bourdieu's reception in the United States (Lizardo, 2012) in which younger scholars are drawing on Bourdieu's practice theory, and especially his concept of *habitus*, while emphasizing experiential, ethnographic methodologies. Lizardo and Strand (2010) refer to this movement as both 'strong practice theory' and the 'French branch' of practice theory. Such practice theorists have drawn on Bourdieu's theoretical work on practice (Bourdieu and Wacquant, 1992), as well as on research from cognitive neuroscience, biology, and psychology, to challenge widely used dialectical models of cultural internalization and externalization. Instead of intuitively appealing 'container models' in which cultural 'software' is seen as stored within somatic 'hardware,' practice theorists rely (explicitly or implicitly) on anti-Cartesian *procedural models* of learning (Lizardo, 2012).

In container models learning is assumed to operate via a process of *transfer* (Lizardo, 2012) or *transduction* (Barsalou, 1999) of sensory experience into disembodied mental information. Sensory experience is transferred/transduced into

cultural software, which is thought to be stored in long-term memory much as a hard drive stores data: in the form of a nonsensory language akin to a binary computer language that is qualitatively different from the sensory experiences that are encoded in it. In contrast, procedural models of learning emerged well after the cognitive revolution of the 1960s–70s as part of a transdisciplinary shift away from epistemological models that treated knowledge in terms of abstract information, and toward models that conceptualize knowledge in terms of embodied skills and abilities. This 'bodily turn' or 'somatic revolution' has taken different forms across disciplines, but it has been pronounced in anthropology, linguistics, philosophy, and sociology. Research within this bodily turn shares a view of learning as situated, embodied enskillment, as *techne* rather than only *episteme*. But for social scientists, possible implications for cultural analysis of this broad shift from theories of culture as *episteme* to theories of culture as *techne* and *habitus*, and from container to procedural models of learning, have yet to be systematically considered. Several programmatic scholarly movements that are reflective of these shifts have emerged in recent years, so in the following Section Theoretical Strategies review some of the recently developed theoretical and also methodological strategies for cultural analysis that are compatible with the turn to embodied epistemologies. I do so with the understanding that in cultural social science as in all social science, theory and method are often interdependent: theories focus researchers' attention on empirical phenomena that are more amenable to analysis with some methodological strategies than with others, while methods contain within themselves metatheoretical assumptions about how social phenomena can be observed and measured. Nevertheless, for heuristic purposes my review of recent cultural research includes separate sections for theoretical and methodological strategies, and I emphasize points of compatibility, potential compatibility, and incompatibility between these strategies.

Theoretical Strategies

How do we learn culture? How is action shaped by culture? And how should social scientists' theories of culture react to recent research on learning, perception, and memory from cognitive neuroscience, biology, and psychology? Many culturally oriented social scientists (including social scientists influenced by Bourdieuian practice theory) simply ignore findings from these fields, while others explicitly reject such findings because of concerns over disciplinary imperialism, theoretical reductionism, and genetic determinism. On the other hand, a steadily increasing number of cultural researchers are choosing to selectively integrate insights from cognitive neuroscience into their work, balancing the potential for reductionism against their desire to ground cultural research on empirically defensible theoretical microfoundations. If culture influences behavior, they contend, then we ought to know something about how culture is learned and remembered in the brain and elsewhere in the body, and how it thereby informs decisions and actions. There are today several contending sets of analytic strategies – that is, sets of theoretical categories and related research strategies – that are informed by ideas from cognitive neuroscience and biology, and that have clear links to sociological practice theory. Three of the most influential such strategies are: (1) distinguishing between 'cold' and 'hot' cognition; (2) distinguishing between deliberative and automatic forms of cognition; and (3) holistic theoretical strategies that seek to identify 'physio-psycho-sociological' (Wacquant, 2004: p. 17) sequences of empirical phenomena.

'Cold' and 'Hot' Cognition

Early proponents of integrating the social and cognitive sciences promoted the importation into social science research of cognitive scientists' categories of 'different kinds of cognition' (DiMaggio, 1997), in particular the categories of 'hot' (emotionally saturated) vs 'cold' (affect-free) cognition. Cerulo (1995, 2010) has argued that this distinction is useful because it opens new avenues for social scientists to study the social structures and contexts that activate hot vs cold cognitive processes, rather than treating those processes as stable traits of individuals. Cerulo finds evidence of sociologically interesting cognition–situation interactions in studies of social movements (e.g., Goodwin et al., 2001) and decision making, and in her own study of national flag designs (Cerulo, 1995).

'Discursive' and 'Practical' Consciousness

A second binary set of types of cognition imported from cognitive science into social science is a distinction between 'deliberative' and 'automatic' forms of cognition. Deliberative cognition (in sociological parlance 'discursive consciousness') is a cognitive system that is slow and deliberate that processes consciously stated values and beliefs. Automatic cognition (or 'practical consciousness') is a system of intuitions that is fast, automatic, and largely unconscious that allows people to operate in ordinary situations without having to constantly reevaluate their goals and strategies (DiMaggio, 2002). Vaisey has been perhaps the foremost proponent of the applicability of 'dual-process' (deliberative vs automatic) models of cognition to social science research. He has demonstrated the applicability of dual-process theory to sociological research in an analysis of survey data on youths' moral values (Vaisey, 2009), while Srivastava and Banaji (2011) have used the Implicit Association Test developed by cognitive psychologists to tease apart deliberative and automatic cognitive processes operating among members of a biotechnology firm (see also Shepherd, 2011).

Maussian Holism

Practice theory and compatible ideas from cognitive neuroscience have led some social scientists not to import binary theoretical categories directly from these fields, but rather to use cognitive science research in support of their arguments for studying social phenomena holistically, from multiple levels of analysis and in non-Cartesian fashion. Drawing from the French strand of practice theory represented by Marcel Mauss (Mauss, 1979/1935, 2006; Ignatow, 2012), Pierre Bourdieu, and Loic Wacquant (Lizardo and Strand, 2010), as well as from cognitive neuroscience research on 'mirror neurons' that shows that people have a capacity to understand the meaning

and intended purpose of others' actions "at an implicit, bodily level, without recourse to an explicit 'theory of mind' of other agents" (Lizardo, 2009). Ethnographers from anthropology and sociology have developed holistic ethnographic strategies that allow them to explore the implicit, embodied pedagogies (Bourdieu, 1990) that characterize both formal institutions and informal social settings (e.g., Desmond, 2006; Pálsson, 1994; Pagis, 2009; Wacquant, 2003) without necessarily distinguishing between different 'types' of cognition or between mental and corporeal phenomena.

Evaluation

The relations between human embodiment and cultural learning and action are complex, and there is no reason to imagine that one theoretical framework or set of theoretical categories would be capable of capturing this complexity in anything like its totality. Yet it is worth noting a few of the inherent strengths and weaknesses of the theories and categories that have developed so far in this area. For theories of embodiment and culture, the key elements that determine these theories' analytic value in empirical research have tended to be their degree of theoretical reductionism (i.e., their conceptual simplicity and elegance) as vs their ecological validity (i.e., their ability to explain real-world social phenomena).

The distinction between hot and cold cognition has proven its analytic value in a number of sociological studies, particularly within the field of social movements research, which for years was dominated by theories that emphasized strategic and instrumental rational action with little consideration of the role of emotions or noninstrumental values and ideals such as justice or dignity. But the turn from 'cold' to 'hot' theories risks amounting to a turn *back* to the century-old crowd psychology of Gustave Le Bon, who analyzed collective behavior as emotionally driven and therefore, ultimately, irrational. This oscillation in intellectual fashion from Le Bon's approach rooted in the body, to mentalistic rational choicelike theories and back again, discourages researchers from building upon older ideas to develop new insights, theories, and methods (Dobbin, 2001). A second, more fundamental critique is that the categories of hot and cold cognition are ultimately rooted in a Cartesian strand of cognitive theory – 'cognitivism' per se – that 'seems to have run its course' (Dreyfus, 2005; Lakoff, 2012). Ethnographic and laboratory studies have demonstrated that bodily, emotional, cognitive, and linguistic capacities do not operate as independent modules, but are rather inextricably intertwined: 'cool reason' depends on bodily and emotional information (see Damasio, 1994), while 'hot cognition' relies on all sorts of cognitive processing (Storbeck et al., 2006; Storbeck and Clore, 2007). Theories of hot cognition may be valuable as a corrective to rationalist/mentalist theories, but in the end they represent an effort to integrate emotions into cognitive sociology within a basically Cartesian framework.

Like theories of hot and cold cognition, dual-process theories potentially exaggerate the modularity (the functional independence) of different types of cognition. This exposes dual-process theories to critiques on grounds of ecological validity, because in practice, deliberative and automatic cognition are not readily identified or distinguished – though it should be recognized that analytic dualism may allow researchers to probe "whether and when the (more) 'mental' becomes (more) 'corporeal' and vice versa" (Vaisey and Frye, forthcoming). A second critique that has been leveled at dual-process theories is that they may be too psychological – too focused on the individual rather than social groups and interactions – for social science research conducted on groups and institutions. Fundamentally, dual-process theories treat cognitive schemas as internal to individuals rather than as products of person–context interactions (Shepherd, 2011: p. 123).

Analytic holism has demonstrated its value as an ethnographic strategy having impressive ecological validity, but a holism that is 'at once corporeal and mental' (Wacquant, 2004: p. 16) also has its weaknesses. In particular, it may not provide theoretical leverage on examining how the 'corporeal' and the 'mental' can influence each other sequentially over time via analytically distinct types of processes. Vaisey notes that if social learning is only ever analyzed, as Wacquant suggests, as *simultaneously* corporeal and mental, researchers cannot investigate the social conditions that cause cognition to become more or less deliberative (Vaisey and Frye, forthcoming). It appears at least at first blush that holistic analytic approaches may be useful mainly for ethnography, a methodology that has great ecological validity but is relatively weak in terms of its ability to identify generalizable patterns within data.

Methodological Strategies

Cognitive neuroscience and sociological practice theory have numerous implications for methods of social science research, having given rise to numerous revisions and reappropriations of extant research methods including ethnographic fieldwork methods, survey techniques, and content analysis methods. These revised and reappropriated methods are in general only loosely and contingently linked with the three theoretical strategies outlined above. Below I review a few methods that have been developed for the study of culture as embodiment, and focus on some of these methods' compatibilities, incompatibilities, and potential compatibilities with the three analytic strategies that have been developed in this area (hot and cold cognition, dual-process theory, and holism).

Surveys

Vaisey claims that one implication of dual-process theory is to cast doubt on the value of ethnographic interview methods for cultural analysis, because, Vaisey contends, such methods "engage with discursive consciousness alone" (2009: p. 1687) and thus do not give scholars much leverage on unconscious cognitive processes. Vaisey promotes fixed-response, forced-choice survey items as a superior method of cultural analysis because such items are more akin to the experience of solving everyday practical problems: forced-choice items potentially tap into practical consciousness, which "has to *make* (as opposed to *discuss*) many such decisions each day" (pp. 1688–1689): "When we hear a survey question, we simply

have to pick the response our practical consciousness prefers, the response that 'feels right' or 'sounds right' to us" (p. 1689).

Vaisey has analyzed survey data from the National Survey of Youth and Religion to demonstrate that people are often unable to articulate reasons for their moral judgments and decisions, but that moral schemas that are a part of practical consciousness are nevertheless predictive of future behavior. In another innovative study based on dual-process theory, Srivastava and Banaji (2011) used forced-choice survey items, supplemented by a laboratory experiment, to examine the interplay of cognition and social networks in a corporation with norms that emphasize cross-boundary collaboration. They found that social desirability concerns induced a disparity between how people viewed themselves in deliberative vs automatic cognition, and that these differences had implications for the resulting pattern of intraorganizational collaborative ties.

Ethnography

Within anthropology and sociology, the study of culture as embodied practice is associated primarily with ethnographic methods. Cultural anthropologists who make use of this framework have studied enskillment, apprenticeship, and socialization within indigenous communities. Pálsson (1994), for instance, uses his ethnographic studies of Icelandic fishermen to argue for a holistic and socially contextualized analysis of enskillment, which he finds has important implications for the economic success of communities as well as for differential success within communities (see also Bloch, 1998; Marchand, 2003; Harris, 2005; Simpson, 2006). Sociological ethnographic studies have focused on embodied dimensions of socialization into modern groups and institutions, such as a boxing gym (Wacquant, 2003), a fire fighting crew (Desmond, 2006), investment banks (Michel, 2011), a congressional political campaign (Mahler, 2011), and the US military (Lande, 2007). Sociologists have distinguished between the primary and secondary habitus, and analyzed how the primary habitus (developed in childhood and adolescence) influences later socialization into an occupational field and the development of an adult occupational habitus (Desmond, 2006). Sociologists have also emphasized the holistic character of shared memories of traumatic events (Spillman and Conway, 2007), the role of the bodily habitus in the negotiation of gender roles (Wade, 2011), and self-transformative practices such as meditation (Pagis, 2009) and religious conversion (Winchester, 2008).

Content Analysis

Content analysis refers to a collection of methods that include both qualitative and quantitative methods for analyzing themes in textual and visual data. These methods are commonly used in sociology, communications research, and political science. The possible implications of practice theory and cognitive neuroscience for content analysis methods in these disciplines have only begun to be explored. Linguists, however, have developed several new subfields that share with practice theory and cognitive neuroscience a holistic view of social actors, and that explore connections between human capacities for language, cognition, vision, emotion, learning, and memory (Feldman, 2006). These subfields include cognitive linguistics (Lakoff, 2012), construction theory (Goldberg, 1995), cognitive grammar (Langacker, 2008), and embodied construction grammar (Bergen and Chang, 2005). Linguists have also developed methods of formal text analysis based on these theoretical programs, such as collostructional analysis (Stefanowitsch and Gries, 2003).

Within the social sciences, Ignatow's quantitative text analysis studies are among a small number of published studies to incorporate practice theory and cognitive neuroscience into the theory and method of text analysis. Ignatow studied embodied metaphors used by programmers through a Durkheimian theoretical lens (2003), collocations of thematically related metaphors and syntactic patterns in transcripts from meetings of shipyard union workers in order to address theoretical questions about cultural coherence and fragmentation (2004), and semantic networks within the moral discourses of religious and secular overeaters support groups in order to investigate the effects of culture on patterns of group membership and participation (2009). While these studies demonstrate the applicability of practice theory and cognitive neuroscience to social science text analysis, the theoretical logic of this approach has not yet been explicated or formalized. As social media makes massive collections of user-generated text readily available to researchers, and as automated text analysis programs increase in power and sophistication, the value to researchers of text analytic strategies that are based on cutting-edge and empirically grounded theories of culture is likely to increase.

Summary

The study of culture as embodied practice rather than as systems of abstract symbols and signs is rapidly entering the mainstream of cultural analysis in anthropology and sociology. It appears to be only a matter of time before social scientists working on topics related to culture – such as learning, memory, knowledge, ritual, and socialization – will habitually take into account the bodily dimensions of their research topics. This article has suggested that up to this point cultural researchers have accounted for the body either by importing somewhat reductionist categories and mechanistic models from cognitive neuroscience, or else by insisting on using holistic, non-Cartesian, and multilevel analytic strategies that risk generating research with very limited generalizability.

As in all social science research, cultural researchers interested in the relations between culture and the body will need to choose the theoretical frameworks and methods best suited to the task at hand, and will preferably do so based on clear-eyed assessments of the tradeoffs involved, particularly tradeoffs between theoretical parsimony, ecological validity, and generalizability. At the same time, it is worth noting that there are voices within disciplines such as cognitive science (Strauss and Quinn, 1998) and psychology (Haidt and Graham, 2009) calling for more holistic and multilevel analyses of cognitive and social psychological phenomena. The sheer complexity and multidimensionality of culture,

particularly when studied as *techne* and *habitus* rather than only as *episteme,* may yet bring the long hoped for consilience of the social, cognitive, and biological sciences a step closer to reality. In the meantime, social scientists are better positioned than ever to understand some of the mechanisms through which culture is learned and reproduced without losing sight of the whole.

Abstract

Embodied cognition (EC) views propose that cognition is shaped by the kind of body that organisms possess. We give an overview of recent literature on EC, highlighting the differences between stronger and weaker versions of the theory. We also illustrate the debates on the notions of simulation, of representation, and on the role of the motor system for cognition, and we address some of the most important research topics. Future challenges concern the understanding of how abstract concepts and words are represented, and the relationship between EC and other promising approaches, the distributional views of meaning and the extended mind views.

Definition of Embodied Cognition

Embodied cognition (EC) theory is intended as a response to the increasing dominance of the classic representational and computational theories of mind (RCTM) in cognitive science. Despite many versions of embodied theories, there are at least two commonalities between all EC approaches. The first is the view that cognitive processes are constrained by perception and motor processes, and therefore that the kind of body possessed by organisms shapes their cognition. The second is the refusal of the information processing model of the mind, and of the metaphor of the mind equated with software that manipulates symbols.

The view that perception and action contribute to cognition is in contrast with the classic view of cognition as separated from sensorimotor control, and that perception, cognition, and action are temporally and functionally independent processes. In contrast to this "sandwich model of the mind" (Hurley, 1998), proponents of EC underline the circularity of these processes, inspiring research programs aimed at showing that action influences both perception (Creem-Regehr and Kunz, 2010; Proffitt, 2006; Witt, 2011) and abstract thought (Goldin-Meadow and Beilock, 2010).

The second tenet, that is, the refusal of the view that cognitive processes involve computations on amodal representations (RCTM), leads to two different variants of EC. The critique advanced by proponents of the first variant is limited to the view that representations are amodal symbols, expressed in propositional format and arbitrarily linked to their referents (Fodor, 1975). In contrast, EC suggests that all concepts rely on the reactivation (or the simulation) of the sensorimotor experience with objects or events they refer to. The propositional approach has indeed to face the symbol-grounding problem (Harnad, 1990). In a nutshell, arbitrary symbols can be grounded only in other symbols, but in order to understand what objects are, we need to exit this vicious circle, 'grounding' the word meaning. The proponents of the first EC variant however, accept the computational side of the RCTM, bridging the gap between RCTM and EC. Accordingly, many EC theorists assume that cognition consists in computations on representation, but endorsing action-oriented representations expressed in bodily formats, including visuomotor, somatosensory, affective, and interoceptive formats (Goldman and de Vignemont, 2009). This EC variant is an improved version of the computational functionalisms on which RCTM is based. A more drastic critique to the second tenet comes from radical versions of EC (REC; Chemero, 2009; Hutto and Myin, 2013; van Elk et al., 2010; Wilson and Golonka, 2013) that refuse the assumption that cognition requires content of any kind. This antirepresentational version of EC abandons the idea that cognition requires content-involving representations and, given the RCTM mantra "no computation without representation", it also discards the computational thesis. Accordingly, REC considers cognition as a dynamical system characterized by continuously and interdependently changing variables that are better described by dynamic system theory (e.g., Spivey, 2007) than by representational explanations.

EC studies cover most areas of psychology and cognitive neuroscience (Borghi and Pecher, 2011; Davis and Markman, 2012; Chatterjee, 2010; Gentner, 2010), including development (Thelen and Smith, 1993), social cognition and emotions (Niedenthal, 2007; Semin and Smith, 2008; Becchio et al., 2010), attention, memory, and language (Barsalou, 2008; Pecher and Zwaan, 2005; Meteyard et al., 2012). Intriguing combinations between different research areas are emerging, including tighter relations between studies on attention, action, and social cognition (Galantucci and Sebanz, 2009; Knoblich et al., 2011). Aside from psychology and cognitive neuroscience, EC theories have developed in a variety of areas, including robotics and computer science (Ziemke, 2002; Arbib, 2006), linguistics (Lakoff, 2012), and philosophy (Chemero, 2009; Nöe, 2004; Hutto and Myin, 2013; Prinz, 2002; Shapiro, 2011).

Perception versus Action?

All EC approaches ascribe a crucial relevance to perception and action. However, the role played by perception or by action for

 http://dx.doi.org/10.1016/B978-0-08-097086-8.56025-5

cognition has been differently emphasized depending on the cultural tradition on which the various approaches relied. The theoretical background of EC can be found in American empiricism and pragmatism and in European phenomenological tradition. Even if some EC approaches underline the role of perception and other stress the importance of action, the two views are not incompatible; in addition, most EC theories emphasize the role of both, arguing that cognition is grounded in the sensorimotor system (see Borghi, 2005 for discussion).

The role of perception has been underlined in particular in research influenced by phenomenology. The "primacy of perception" was stressed by early phenomenologists, including Husserl and Merleau-Ponty, and inherited by contemporary phenomenologists (Gallagher and Zahavi, 2008). Furthermore, phenomenology impressed some of the early proponents of embodiment theories (Varela et al., 1991; Thompson, 2007). Finally, the interest in phenomenology offered new tools to study the body and its extensions (e.g., Berlucchi and Aglioti, 1997; Umiltà et al., 2008) and the relationship between the body and the self, stressing the dichotomy between body schema and body image, and that between sense of body ownership and sense of agency (Tessari et al., 2010; Tsakiris et al., 2007). The role of perceptual aspects has also been emphasized relying on the empiricist philosophical tradition, in particular on the work of Hume and Locke. Work by Barsalou and, on the philosophical side, by Prinz (2002), is in continuity with this tradition. According to the Perceptual Symbols Theory (Barsalou, 1999), no transduction process from sensorimotor experience to symbolic knowledge is necessary. Perceptual symbols, the building block of knowledge, have the combinatorial and productivity characteristics of arbitrary symbols, but they are modal rather than amodal, because they reflect the sensory qualities of the perceived entities. Stressing the role of perception has led some authors to remark the fact that bodily states do play a role but not an exclusive one. For this reason Barsalou and collaborators have proposed using the label 'grounded cognition' instead of 'embodied cognition' to underline the fact that cognition is grounded in a variety of situations, situated simulations, and not only in bodily states (Barsalou, 2008; Pezzulo et al., 2011).

The American pragmatist tradition and the ecological psychology of Gibson (1979) represent the theoretical background of the approaches that put a strong emphasis on action for cognition. Furthermore, an emphasis on the role of the motor system and of the overt behavior comes from the ordinary language philosophers, such as Gilbert Ryle and the late Wittgenstein. As nicely summarized by Wilson (2002) at the beginning of the EC wave, the principle underlying EC is that "knowledge is for action" – knowledge is both grounded and oriented to action. Accordingly, many authors described EC as a pragmatic turn in cognitive science, according to which cognition should not be understood as providing models of the world but as subservient to action, being grounded in sensorimotor coupling and in the ongoing interaction with the external world (Engel et al., 2013). In psychology, work on memory and on language grounding by Glenberg exemplifies this motor-oriented approach. In his BBS paper of 1997, significantly entitled "What Memory Is For," Glenberg argued that memory has an important adaptive role to support us in situated actions.

In neuroscience, the role played by the motor system in perception and cognition was emphasized by the research on the mirror and canonical neurons (Gallese et al., 1996; reviews: Rizzolatti and Craighero, 2004; Rizzolatti and Sinigaglia, 2010). Mirror and canonical neurons are located in the motor system and contribute to action execution. However, they support different cognitive processes. Mirror neurons are activated during the execution of a specific action and the observation of the same action performed by another agent, thus suggesting that the passive observation of actions recruits the corresponding motor representation in the observer motor system. After their discovery in different stations of the motor system, including the primary motor cortex, other similar mirror mechanisms have been found in emotional and sensory areas, suggesting that the perception and comprehension of others' intentional actions, emotional expressions, and somatosensory experiences depend on an implicit and automatic simulation within the sensorimotor system (see Buxbaum and Kalenine, 2010 for an embodied view according to which mirror neurons are not sufficient for comprehension of actions). The interpretation of the mirror neuron system offered by the Embodied Simulation theory (Gallese, 2001), according to which the observation of others' behavior triggers an automatic, subpersonal, and preconceptual simulation, provides an embodied account of intersubjectivity, in antithesis to the two cognitivist explanations of the theory of mind abilities (the theory–theory and the simulation theory). Furthermore, the mirror mechanisms opened new important perspectives in research on cognitive processes such as language comprehension and imitation, as well as a new key to interpret the social deficit in autism. Canonical neurons are premotor neurons that discharge both when interacting with objects and when passively observing them. Their discovery supports the view that perception involves the motor system and, in particular, the preparation of possible interactions with objects. This discovery contributed to launching studies and research on object affordances.

Ideomotor theories (Prinz, 1997) represent an important family of theories investigating the relationship between perception and action, and the goal-directed character of action. According to one of the most influent ones, the Theory of Event Coding (TEC) (Hommel et al., 2001), perceived events and actions rely on common representational structures, that is, they are represented by a network of feature codes. TEC predicts that perception is facilitated in case of overlap between the action an organism perceives and the action he or she is able to perform. Evidence in support of ideomotor theories ranges from imitation to attention to social cognition. For example, the compatibility between observed actions and responses influences the attribution of personal traits: finger-key responses lead to faster identification of individuals typing rather than performing sporty activities (Bach and Tipper, 2007). The mirror neuron system represents the neural underpinnings of ideomotor theories: our brain resonates more when observing actions we can reproduce than unknown action. Motor resonance has been documented in a variety of areas; a notable one concerns

empathy for others' pain (e.g., Avenanti et al., 2010; Iacoboni, 2009).

The Notion of Simulation

The concept of simulation was originally introduced in the field of social cognition, to account for our folk psychological abilities to predict others' behavior by ascribing mental states. This account was intended as a response to the theory–theory perspective, which conceives folk psychology as a theoretical and observational enterprise, suggesting that mindreading is rather based on using ones' own subpersonal models as the measure of everyone else's. In a seminal paper, Gallese and Goldman (1998) suggested a possible role of mirror neurons in mental simulation. More recently, theorists differentiated between an explicit (non-embodied) simulation, based on the view that simulation depends on a deliberative inference, versus an implicit, embodied simulation involving subpersonal activation of mirror mechanisms and shared representations (Gallese, 2005). Both versions were criticized by proponents of REC, suggesting that the resonance processes, including the mirror mechanisms, are part of the processes that underlie intersubjective 'direct perception' rather than simulation (Gallagher and Zahavi, 2008).

Besides of its use in social cognition, the concept of simulation was also used to account for the recruitment of the same perceptual, motor, and emotional system during the interaction with objects and entities in the world, as well as during imagery and language comprehension. Starting from this general idea, this notion now has a variety of connotations, also due to the different nuances that EC has assumed. Some authors intend simulation as a form of reenactment "of perceptual, motor, and introspective states acquired during experience with the world, body, and mind" (Barsalou, 2008), while others, underlining its predictive aspects, prefer to use the term 'motor simulation', intending it as a form of action preparation (Gallese, 2005; Grush, 2004). In addition, while some authors underline the implicit, automatic aspect of simulation (Jeannerod, 2006), others tend to equate it with a form of (motor) mental imagery, which may occur *a posteriori* (Decety and Grèzes, 2006). Finally, in their attempt to highlight dynamic and flexible aspects of cognition and to reject representations, REC avoids using the notion of simulation, particularly if intended as a form of reenactment.

The Agenda

EC theories have received ample support in a variety of domains. We will refer to some important areas, with no pretense of being exhaustive.

Affordances

The notion of affordance (Gibson, 1979) refers to the fact that objects invite organisms to act and suggest actions. For example, apples suggest grasping to humans, but not to worms. Affordances are therefore interactive properties, emerging from the relationship between organisms and environment, and pertain at the same time to perception and action. In the last years many studies have focused on affordances and 'micro-affordances', a term introduced by Ellis and Tucker (2000) to highlight both continuities and discontinuities with Gibson. Microaffordances are more specific that Gibson's affordances: they refer to action components (e.g., grasping) suitable for specific objects, thus implying object recognition. Furthermore, while Gibson's view is externalist and not focused on brain representations, microaffordances are neural representations corresponding to patterns in the brain of conjoint perception and action experiences. Numerous studies have demonstrated that observing objects activates affordances (e.g., grasping actions); recent work on affordances highlights their flexibility and contextual dependency (review: Thill et al., 2013).

Concepts and Words

According to all EC views, concepts and language are grounded in perception, action, and emotional systems (reviews: Coello and Bartolo, 2012; Fischer and Zwaan, 2008; Gallese, 2008; Jirak et al., 2010; Willems and Hagoort, 2007; special issues: Cappa and Pulvermüller, 2012; Cangelosi and Borghi, in press).

The influential Perceptual Symbols Theory (Barsalou, 1999) states that understanding concepts depends on the ability to form and use simulations. Thus, to decide whether a telephone rings we need to form a multisensory simulation. The phone ring is not stored in propositional terms, as a mental word; rather, it is the acoustic record of previous experiences with phones. This view received great impulse thanks to studies on representation of categories in the modal areas of the brain (Martin, 2007). EC views contrast with domain specific approaches, according to which in the brain there are innate categorical subsystems. Rather, concepts are intended as modality-specific distributed and flexible representations (Kiefer and Pulvermüller, 2012).

In continuity with this view, Zwaan (2004) proposes that comprehending language implies activating a simulation involving the motor system (see also Kemmerer, 2006). Many experiments have demonstrated that the activation in perception and motor areas during language comprehension is sensitive to the effectors (foot, hand, mouth), to kinds of affordances, to the bodily space (Ferri et al., 2011), to the direction implied by sentences (toward vs away from the body) (Glenberg and Kaschak, 2002), and to the emotional connotations of words (we tend to attract positive words and reject negative ones, Chen and Bargh, 1999); furthermore, it is highly flexible and sensitive to the context (van Dam et al., 2012).

In the strong EC perspective proposed by Glenberg (1997), concepts support us in selectively focusing on affordances allowing us to interact appropriately with objects. Hence, concepts are constrained by the kind of body we possess; for example, we conceive cups in terms of their distance from us, weight, and so forth – more generally, in terms of what we can do with them. Gallese and Lakoff (2005) argued that concepts and language exploit at a more sophisticated and higher level the multimodal character and the basic structures of the sensorimotor system (Anderson, 2010). In continuity with these views, Glenberg and Gallese (2012) have proposed that mechanisms of motor control have been exploited for language learning, comprehension, and

production (on the involvement of the same systems during language comprehension and production, see also Pulvermüller and Fadiga, 2010; Pickering and Garrod, 2013; on the idea that language evolves from manual gestures, Gentilucci and Corballis, 2006).

Body and Emotion

Given its disembodied view, cognitivism rarely paid due attention to the study of the body. In contrast, EC recovered some conceptual distinctions from phenomenology and neuropsychology, thus allowing neuroscientific investigations on the bodily experience and providing new insights on topics such as tool use, agency, and emotion.

The recovery of the distinction between body image and body schema, the former being a mental construct or a set of beliefs about the body, and the latter being a nonconscious model that monitors posture and movement (Gallagher and Zahavi, 2008), brings to a deeper understanding of different psychological disorders. At the same time, it shows that a number of objects, including prostheses and tools, can be incorporated into the body schema and perceived as part of one's own body. Notably, neurophysiological and neuropsychological evidence showed that the use of tools operating in the far space entails the updating of the map of the body schema and, as a consequence, it extends in the new operational space the peripersonal space anchored to the body (Maravita and Iriki, 2004). The above-mentioned distinction between sense of ownership and sense of agency (Tsakiris et al., 2007) is a further phenomenological distinction adopted by EC researchers, which has been largely used in the study of the bodily self, becoming a useful tool in the study of mental disorders such as schizophrenia (Ferri et al., 2012).

Finally, the attention to the bodily representations breathed new life into the debate on emotion. EC retrieved and renewed the somatic theory proposed by William James, according to which the emotional experience consists in the central representation of the bodily response to an emotional stimulus. New evidence revealed the existence of an afferent neural system that represents the physiological condition of the physical body (interoception), thus constituting a central representation of the 'material self' founding subjective feelings and emotions (Craig, 2002). Remarkably, this new link between interoception and emotion suggested that different psychological disorders, including neuroticism, social phobia, anxiety, and eating disorders, could be dependent on anomalous interpretations of the bodily interoceptive feedback. At the same time, the link between body and emotion contributed to the formulation of the 'facial feedback hypotheses' (Niedenthal, 2007), according to which the facial feedback affects the emotional experience; it follows that the motor production of emotional expression is part of the emotional experience, as predicted by early American pragmatists (Caruana and Gallese, 2012).

Critiques and Debates

EC has been the object of a lot of criticism. One of the most debated issues concerns the role played by the motor system in concepts and word processing. In an influential paper, Mahon and Caramazza (2008) argued that, even though the evidence showing that the motor system is involved in conceptual and language processing is indisputable, it can be explained through activation spreading from 'disembodied concepts' to the sensorimotor system interfacing with them. Hence, the role played by the sensorimotor system would be only epiphenomenal and not necessary for language comprehension. If it was necessary, then disruptions of the sensorimotor areas should impair language processing.

In contrast with this view, EC proponents argue that the motor system involvement is constitutive of the process. This is supported by evidence showing that the motor system activation occurs early, in an automatic, bottom-up fashion, and that it is somatotopic, that is, different areas of the brain are activated during processing of words related to action with different effectors, such as arms, legs, and mouth (pick, kick, lick) (Pulvermüller, 2005). The discussion is still open, however, because there are some controversial results. For example, not all studies have found early activation of the motor and premotor cortices during language processing; in addition, even if the motor system is modulated during language comprehension, there is evidence of both interference and facilitation (Willems and Franken, 2012); finally, evidence on patients is clear (review: Pulvermüller and Fadiga, 2010), but some clinical studies suggest that motor system lesions do not always lead to comprehension impairments. An interesting solution to this debate is advanced by enactivists (van Elk et al., 2010). As it has been proposed, the issue of necessity implies the idea that words are characterized by a core meaning, but enactivists underline that words are action oriented and contextual dependent, and that the human brain is plastic. This makes it possible to predict that comprehension is also possible when sensorimotor activation during language comprehension does not imply forms of reenactment.

Future Challenges

Some of the most important challenges for EC concern the explanation of abstract concepts and the relationship with other approaches, as the distributional approach and the extended mind view. One of the main challenges of EC is to account for concepts and words without concrete referents, such as 'phantasy'. Several EC theories of abstract concepts and words (ACWs) have been proposed (review: Pecher et al., 2011; special issues: Borghi and Pecher, 2011; Tomasino and Rumiati, 2013). Some views underline that the systems involved in concrete word representation are responsible also for representation of ACW, since not only concrete but also abstract words activate the motor system. Other EC theories underline the differences between concrete words and ACWs. The most influential theory claims that abstract concepts are represented in terms of concrete ones, through the mediation of metaphors (Lakoff and Johnson, 1999); for example, the abstract notion of time is explained in terms of the concept of space (Casasanto and Boroditsky, 2008). According to another view, ACWs differ from concrete ones due to their content: ACWs rely more on

situations and introspective features (Barsalou, 1999), and activate more emotions (Vigliocco et al., 2013). Recently multiple representation theories have been proposed (Dove, 2011; Barsalou et al., 2008). For example, according to the Words As Social Tools (WAT) view (Borghi et al., 2011; Borghi and Binkofsky, in press), both concrete words and ACWs are grounded in sensorimotor systems; however, for ACWs linguistic information plays a major role, due to their acquisition modality: they are primarily acquired through words rather than through interaction with their referents, and verbal labels help assemble sparse sensorimotor experiences.

Promising future directions concern the relationship between EC and two views emerging in different areas (computer science and philosophy), that is, distributional approaches (DA) to meaning and extended mind (EM) views.

DA and EC have been typically considered as antithetical. For example, according to the embodied Indexical Hypothesis (Glenberg and Robertson, 2000), words' referents evoke affordances, and these affordances constrain the relationships between words. In DA, meaning derives from the statistical co-occurrence of words in text corpora: from the relationship between associate words (real words, not mental words), not between words and their referents. Therefore words are not embodied, and the symbol-grounding problem is present. This distributive information is, however, able to account for many empirical findings, such as semantic priming effects. Recently some hybrid approaches have been proposed (review: Andrews et al., 2013). In hybrid views, conceptual processing is both linguistic and embodied, depending on the task (Louwerse, 2011). In EC multiple representation accounts, instead, access to meaning occurs only through simulation, but linguistic shallow tasks such as lexical decision can be performed without necessarily using full embodied simulations: linguistic distributional information can be used as a shortcut, allowing fast responses (Barsalou et al., 2008; Connell and Lynnot, 2013).

According to the extended mind (EM) view, the mind is not limited within the boundaries of our head/brain but is rather distributed in our brain, body, and external devices, which possess the power to augment our computational abilities (Clark and Chalmers, 1998). Even if many proponents of the EM view favor an embodied view, EC and EM views are typically considered independent perspectives, both because EM is more widespread in philosophy than in neuroscience and because of its functionalist flavor (Kiverstein and Clark, 2009). However, interesting convergences between these two areas are emerging (see Borghi et al., 2013; Borghi and Cimatti, 2010; Clark, 2008), particularly in research on the sense of the body and on bodily extensions.

Emergency Relief and Social Work Responses

Desley Hargreaves, School of Social Work and Human Services, University of Queensland, Brisbane, QLD, Australia

Abstract

This article is a practice-based reflection on the role social workers can play at the strategic and service intervention level when responding to disasters and emergency events. It discusses two significant events which impacted Australia – the Bali bombings in October 2002 and Victorian bushfires in February 2009 – and shaped policy responses by government. It outlines the lessons learned by social workers from this involvement. The profession needs to examine how it can take a stronger leadership role in emergency response and recovery.

Introduction

On 12 October 2002, 88 Australians died as the result of a terrorist attack at two popular night spots for tourists in Bali, Indonesia. Social workers in the Australian government agency Centrelink (now incorporated into the Commonwealth Department of Human Services – DHS) became a critical part of the onshore response. In May 2003, Centrelink social workers began providing support offshore to families and survivors attending the trials of the bombers in Bali. In February 2009, the Australian State of Victoria burned: 173 people died and over 2000 homes were destroyed. Some communities suffered major loss of critical infrastructure, homes, and community gathering places. Social workers found themselves on the front line of the nation's and the state's response. This article tells their story to illustrate what social workers can offer in disaster response. Building on insights gained from involvement in a range of disasters and emergencies, and knowledge the profession has developed since the 2004 Indian Ocean Tsunami and 2005 Hurricane Katrina in the United States, I illustrate how in times of national trauma, social work can position itself at the center of relief and recovery efforts. I suggest that the profession should examine how it can be more strategically represented in emergency response and recovery.

There is much debate about definitions of disaster (Dominelli, 2012; Kreps, 1995) albeit within a consensus that they tend to be overwhelming, often sudden in onset, cause significant damage, and possible loss of life, beyond the capability of the affected area to respond and therefore requiring outside assistance in response and recovery. For this article, I use the following:

> A serious disruption to community life which threatens or causes death or injury in that community, and damage to property which is beyond the day-to-day capacity of the prescribed statutory authorities and which requires special mobilisation and organisation of resources other than those normally available to those authorities.
> Emergency Management Australia Glossary, 1998: pp. 22–23

Disasters can happen anywhere and occur often without warning. Many natural disasters are being attributed to the effects of climate change and global warming. Since the beginning of the twenty-first century, many parts of Australia have experienced floods, bushfires, cyclones, severe weather events, equine influenza outbreaks, severe drought, and minor earthquakes. Australia experienced the impact of terrorism when Australians died in the World Trade Center attack in 2001. However, the Bali bombings outraged Australians who felt their traditional sense of safety and security threatened in a country that had long been a favorite holiday destination. This event set a new direction for the Australian government's response to survivors and families of deceased, and those killed or injured overseas as a result of terrorist events or natural disasters.

Overview of the Literature: Social Work and the Response to Disasters

There is a strong body of literature on the human response to and experience of disasters and emergencies. There is also an increasing body of literature about social work and disasters (Rowlands and Tan, 2008; Taubman and Weisz, 2011; Dominelli, 2012). Raphael (1986) researched the human responses to the different phases of disaster and discussed in some detail the recovery trajectory for individuals and community. This seminal work was based on her research on the social disconnection which occurred with the evacuation of families from Darwin following Cyclone Tracy. Her findings on this issue link closely with the work of Hobfoll et al. (2007). In their review of the empirical evidence of the five essential elements of immediate and mid-term mass trauma intervention, they identify the 'Promotion of Connectedness' (pp. 296–298) as of central importance. They discuss the body of research that identifies the constructive role that social support can play in combating stress and trauma.

Mathbor (2007) has written about the role social workers can and should play in preparation and planning for response as well as in the recovery effort. In this article, he discusses social capital and the challenges of mobilizing networks, contacts, and cohesion after a disaster has occurred. He also identifies the work needed at times to focus community collaboration, coordination, and use of existing networks to support effective service delivery. Mathbor (2010) further highlights skills and training that social workers need to work effectively and within their role in the recovery effort.

Dominelli (2012) proposes that boundaries between natural and hu(man) made disasters are becoming increasingly blurred. She examines different kinds of disasters, the geopolitics behind them, and the unsustainability of current forms of industrialization, and challenges the social workers to become more strategically involved.

Zakour (2005) discusses the varied roles that social workers play in disasters and reflects on their contribution to various research agendas. He notes the focus on responding to the social disruption brought about by disasters and emergencies and discusses the concepts of vulnerability at both the individual and community level. Social structural factors including poverty and social isolation would traditionally be a focus for social workers. He notes that in ensuring improved access to services and resources, social workers engage in a range of activities such as case management, brokerage, advocacy, and outreach. He also discusses the contribution social workers make in organizational and interagency networks.

Themes such as grief and loss, trauma, strengths-based interventions, and resiliency have received much attention. Tedeschi and Kilmer (2005) highlight the move in thinking from a deficit to a strengths approach in clinical practice. They further discuss concepts of resilience and the possibility of growth after trauma. This reflects work by Richardson (2002) where his review of articles focuses on the work that examines individual strengths that can be used to assist people to cope with and develop through their experience of trauma. This is further reinforced by the work of Walsh (2007) who brings those concepts into the field of traumatic loss and major disasters. Concepts of hope building are also identified as important.

Cronin et al. (2007) offer a useful analysis of the American Red Cross staff support program and comment on the lead role that social workers could play in providing support programs not only in disasters but also in caregiver support. Alston (2013) and Enarson and Meyreles (2004) bring a focus to the gender dimension of emergency response both from a historical and a geographical perspective. Both articles identify the risks of ignoring this dimension in planning for and responding to the effects of disasters.

Social Work and Disaster Services in Australia

Australia is fortunate to have a Social Work Service located in a critical Commonwealth (Federal) government service delivery agency. The Social Work Service comprises approximately 700 professionally trained social workers within an agency of approximately 35 000 staff, delivering income support, child support, health, and related services to millions of Australians. These social workers are located in customer service centers, call centers, and other national teams across Australia. In the two examples cited earlier, the Social Work Service was able to position itself in the very early days as an integral part of the response from the strategic to the tactical and operational levels. This was contrary to the structural arrangements previously in place in the Department.

The concept of social work involvement in responding to emergencies and disasters is not new. Social work literature on this work has increased significantly over recent years (Rowlands and Tan, 2008; Mathbor, 2007; Dominelli, 2012). Social workers play a critical and often unrecognized role in the early recovery period, as well as in supporting individuals, families, and communities in the longer term. In Australia, social workers are involved at the Commonwealth, State, and local level as part of the psychosocial recovery arrangements. In the UK, social workers are statutory second responders after people have been evacuated, along with health providers (Child et al., 2008). Tan et al. (2011) highlight the involvement of social workers in both China and Taiwan in responding to various disasters but express concern at their lack of training for the task. Iravani and Ghojavand (2005) discuss the positive role social workers have played in Iran and Taiwan following disasters.

Each country has a process for responding to disasters whether formalized or reactive. In Australia, a formalized approach has been refined over many years, since Cyclone Tracey struck Darwin on Christmas Day in 1974. This led to the development of national, state, local government, and local district planning guidelines for emergency response and recovery. Australia has been supported in this by a formal agency – Emergency Management Australia – which sits within the Commonwealth Attorney General's Department.

Policy Responses

Tarrant (2006) notes that a disaster is a very complex policy problem which cuts across all levels and functions of government. The Australian government has shaped its policy response to disasters and other emergencies based on its experience of different types of disasters over many years. Feedback from constituents, those impacted by disasters, workers involved in community recovery, and evidence-based research has also shaped the changing policy response in Australia. Formal arrangements exist between the Commonwealth and State and Territory governments which activate the flow of funds and other assistance depending on the scale and nature of the disaster. It also provides a Commonwealth payment known as the Australian Government Disaster Relief Payment. This is made available to individuals through the Commonwealth DHS based on a declaration by the Attorney General. A similar arrangement exists in the US (FEMA, 2012).

With offshore crisis responses, the nature of the assistance has been determined by government specific to each circumstance. The Bali bombings resulted in a package of assistance including medical, funeral, financial, and support services onshore, as well as the provision of financial and support services offshore when the families of victims and survivors were funded to attend the trial of the Bali bombers. In 2012, the Australian Parliament passed a legislation which provides financial compensation for victims of offshore terrorist events – a further step by government to fine tune its policy response to a specific cohort of victims and survivors.

The Family Support Team – Support to Australians Impacted by Offshore Disasters or Terrorist Events

Following the Bali bombings, the Centrelink Social Work Service established a case management service (the Family Liaison Service) which provided a coordinated whole of

Commonwealth government response to families of the deceased and survivors in Australia. Initially this service played the role of a safety net service as Red Cross Australia provided a service for the first 12 months after the bombings. The safety net was intended to cater for those affected who did not wish to engage with Red Cross or other service providers but required support to access the range of assistance available. Centrelink social workers in locations where survivors and families of the deceased lived, undertook this family liaison officer role in addition to their usual role within the agency.

At the request of the Interdepartmental Emergency Taskforce (IDETF) chaired by the Department of Foreign Affairs and Trade (DFAT), social workers were deployed to Bali for the first time in May 2003. This was an entirely new type of work. Centrelink had never delivered services offshore previously and there was considerable organizational risk, pushing the boundaries of the agency's remit. Staff operated with the ongoing threat of further bombs. They worked in another country – different jurisdictions, different cultures, very humid climate, health risks (SARS), and at least 8 h flight from their support service. Being Australian potentially made them a target for attack; so engaging appropriate security protocols with the advice of the Australian Federal Police (AFP) who had a long-standing relationship with Indonesian National Police was mandatory.

The deployment was for a period of 7 months to provide personal and psychosocial support to those attending the trials. These staff members worked in gender-balanced pairs and were rotated every 3 weeks throughout that period. The role was developed, clarified, and negotiated within a very short time frame by Centrelink's chief social worker during an urgent trip to Bali, prior to the first social workers being deployed. Because this work fell outside the normal operations of the agency, the Social Work Service needed to negotiate access to funding, develop guidelines for deployment, remuneration, occupational health and safety arrangements, administrative arrangements, communication options, and set up daily supervisory and immediate support access arrangements for the staff offshore.

Subsequently a Family Support Team (FST) was established comprising social workers who could be deployed offshore as part of the Australian Government's Emergency Response team. They worked alongside consular and other staff from DFAT, the AFP, and a range of staff from other key departments who were deployed as part of the broader response team. A critical element of FST work is based on the social work practice principle – 'Start where the client is' (Goldstein, 1983). Bearing witness is often the starting point. In their article 'After the Wave,' Manning et al. (2007) note that practical assistance is a key component of effective recovery. This creates an opportunity to start trust building. This was particularly important when the FST had a period of 7 days to work with affected people. This was the period funded through government assistance, for people to travel offshore to be with, locate, or commemorate their loved ones. The FST provided supportive intervention to assist people to make necessary decisions within a short time frame and develop some basic coping strategies until they could return to their usual support network in Australia. Such decisions could have been about whether to stay or go home when it became clear that the Disaster Victim Identification, a long and painstaking process, could stretch into weeks. It could have been about where the body of a loved one should be returned to, whether cremation was the preferred option, or whether to visit the site of the tragedy.

The initial deployment informed the role undertaken by social workers for the first anniversary commemorations where the government funded over 500 families and individuals to attend the services in Bali on 12 October 2003 as well as in Canberra a few days later. Centrelink sent 11 social workers to Bali for this event. Centrelink's chief social worker headed up a team of 28 staff from four different departments and agencies who provided support to family members and survivors. For the Canberra service, a senior manager in the Social Work Service led the family support arrangements. Social workers were involved at the strategic (IDETF and agency Executive) and tactical level in influencing the development of the policy response, providing feedback on anomalies, sourcing and providing feedback from families, and shaping and providing the service delivery response.

Subsequent to that, social workers at all levels have been an integral part of recovery efforts onshore and critical response services offshore. These have included deployments to Thailand and Sri Lanka following the Indian Ocean Tsunami, to London and Bali after the 2005 bombings in both locations, and associated anniversary events including the tenth anniversary of the 2002 bombings in October 2012. Social workers were deployed to Cyprus and Turkey to support evacuated Australians during the Lebanon crisis in 2006, to Yogyakarta, Indonesia, and Papua New Guinea following crashes of civilian aircraft, and to Jakarta and Mumbai following terrorist events there. Further deployments included those to Frankfurt to meet evacuated Australians during the crisis in Cairo (2011), to New Zealand following the mine collapse at Pike River in 2010, Christchurch following the earthquake in 2011, and Japan following the earthquake, tsunami, and nuclear event in 2011. The social work role has remained consistent with that originally developed for Bali. In all of these deployments, social workers played significant leadership roles in providing advice about psychosocial impacts, delivering services on the ground, and contributing to the shaping of the government's policy response. Providing feedback on the impact of policies and policy anomalies has been an essential and valued role.

Service integration is critical. The FST social workers' short-term offshore intervention is supported by the longer-term onshore Family Liaison Service which links people to appropriate support services in their local community. The staff who deploy offshore facilitate direct referrals of families or individuals to their onshore colleagues so that people do not have to tell their story more than once to get help, all Commonwealth assistance is coordinated through one person, and people are linked in to local services that can respond to their needs. These local referrals can vary from assistance with the execution of wills and finalization of estates through to interventions from qualified trauma professionals. This integration also includes the other agencies with which staff work offshore in the response. There are always challenges in managing such relationships, but doing so is essential to ensuring a seamless service for those affected.

The literature review highlighted the fact that social connection is crucial to effective recovery. The experience of FST

social workers working offshore has been that it is important to identify those who lack support or where support networks are very fragile, and prioritize time with them. Some people seek contact with others who have been affected by the same disaster. One part of the social work role has been to facilitate such contacts – usually informal gatherings at a café or hotel. Others have preferred to manage their grief in private away from the scrutiny of the media or well-intentioned support services. Social workers need to be wary about mistaking solitude for desperate aloneness. Men and women demonstrate different help-seeking behaviors in these circumstances. Responding appropriately can be challenging.

The Victorian Bushfires

Following the devastating bushfires on 7 February 2009, the then Prime Minister of Australia and the Premier of Victoria announced on 10 February that everyone affected by the fires would be allocated a case manager within 24 h of registration with what became known as the Victorian Bushfire Case Management Service (VBCMS). The service did not exist at the time of the announcement nor was a registration process in place. Social workers took a leadership role in the development and delivery of VBCMS. It had to be operational within 3 days of the announcement. It was unclear how many people would require assistance. The announcement was quite open-ended – anyone affected by the fires. Under the emergency management arrangements, the Victorian government was in charge of the recovery arrangements. The Commonwealth government supported in many ways but was not in charge.

Two Senior Executive staff from the Victorian DHS (DHS Vic) were assigned to manage the establishment of the service. At the Commonwealth level, Centrelink's chief social worker was re-assigned to work with the two Victorian Executives to develop and operationalize the service. All three staff were social workers with backgrounds in disasters, human resources, and case management. The potential for sensitivities in Commonwealth/State relationships could have interfered with the task but a very constructive, collaborative working relationship developed. This was supported by the deployment of a number of staff with social work skills to key positions to support the three Executives in the development of VBCMS. Challenges included developing a shared understanding of what a case management service would deliver (including standards, quality assurance, registration process) and finding staff with appropriate skills to undertake case management at very short notice. At a practical level, it was easier for the Commonwealth to mobilize its employees quickly. The first case managers were deployed on 13 February as the case management service structure developed around them. At the end of the first week of operation, a client database had been deployed, 2428 registrations had been received, 100 case managers were employed, and 1207 cases were assigned. A resource kit and core training had been developed and was being delivered. By 31 March, all cases were finally allocated.

Such a large-scale and combined Commonwealth/State case management response had never been undertaken before in Australia. Staff redeployment from across the country to many affected communities within Victoria required highly organized and structured management arrangements. DHS Vic negotiated with its service partners that were funded to deliver a range of social services on its behalf to also undertake case management roles. Many convincing arguments were required as the Executives met with Regional Executive groups and Community Service Organizations. This was not ordinary community recovery work.

The three Executive staff remained fully involved for the first 10 weeks before starting to hand over responsibility to other senior staff. This hands on approach assisted in risk mitigation and management and enabled troubleshooting to occur quickly, in a highly volatile political environment. Governance structures were established quickly and daily meetings at all levels of the service operations ensured communication of key messages was reinforced and feedback could be responded to urgently. Because of the size and complexity of the Commonwealth response, a Commonwealth Professional Services structure was established, identifying lines of accountability, professional support, and supervision. The Commonwealth also operated the VBCMS call center for registering clients, staffed by 25 social workers. A number of affected people moved interstate. To ensure consistency in case management provision for these people, Centrelink social workers in the area closest to where the person had relocated, provided this service under the auspice of VBCMS.

The VBCMS was designed to operate for 2 years. Over 70 agencies worked under its banner providing over 450 case managers. The Commonwealth provided the initial surge capability with case managers building up to 105 and withdrawing in stages as the local community service organizations successfully recruited case managers. The Commonwealth officially withdrew its case managers at the end of December 2009 as cases were handed over to the local community service organizations for follow up. Leadership, relationship management, stakeholder management, and communication were essential to the development and continuing operation of the service. Working collaboratively – being respectful of each other's role – was critical.

It is well understood in the disaster literature that most people will recover from disaster without professional intervention. Most people turn first to their normal social networks for support (Kaniasty and Norris, 2004; Hobfoll et al., 2007). Connecting them becomes a critical role when these normal networks are disrupted by the event. The Victorian bushfires created some major disruptions as whole communities were damaged and people were relocated and disconnected from their normal social networks. The role of case managers was crucial in reconnecting, ensuring community information was provided, and facilitating attendance at meetings where the future of communities was being discussed.

Lessons Learned

The role of social workers in leadership is an important one. Social work leadership takes place at all levels in an emergency from strategy to delivery on the ground. A clear decision making and reporting structure needs to be established quickly. This is often described as a command and control leadership style and important in helping to bring some sense of order for staff to the environment in which they will be working. This

was very evident in the response to the Victorian bushfires where the task seemed overwhelming. Consensus decision making did not lend itself to the need to respond to the situational ambiguity as fires continued to burn, and policy and political imperatives kept changing. This style is one that does not sit easily with social workers but experience over many years has shown that once these arrangements are in place, staff can focus more on the actual service delivery rather than the uncertainty of the environment within which they are operating. Role clarity is equally important as are the staff support arrangements. Daily debriefs and operational reviews enable the service to be tailored to constantly changing needs and staff members are key contributors to these decisions. The conduct of these is a clear leadership responsibility.

For social workers returning to their normal work and home environment after the intensity of involvement in an emergency response, the adjustment back to what used to be normal can be very challenging. The disaster becomes a point of reference in people's lives and all involved are impacted and changed in some way by what they have seen, heard, experienced, and done. This highlights the importance of quality professional supervision, good staff support arrangements, and appropriate follow up.

Social workers operate as part of a broader team in such recovery efforts. They bring a unique perspective to the assessment of need which is ever changing as the disaster unfolds and the recovery effort ramps up. The concept of integrated, collaborative service delivery is critical to supporting those impacted.

The purpose of the intervention in these situations is to help people to create some order out of chaos and regain some sense of control of their lives, and over time to find some meaning and hope out of something catastrophic. It is critical that social workers understand their role, the context in which they are working, and the stage of the response in which they are involved.

Building social connectedness is an important intervention but it can be challenging to connect and create a way forward. Traditional divisions in families and the community become evident fairly quickly, comparisons are made about the level of assistance received, and notions of 'deserving' and 'undeserving' emerge (Kaniasty and Norris, 2004). The real challenge is in identifying those people who have lost or never had any social support networks and supporting them to re-engage with or access mainstream support services. These are often individuals or families who have poor help-seeking behaviors and who can be socially marginalized.

Support needs can increase when the disaster has gone off the front page and generally people think that it is time for those affected to get on with their lives. Even some of the strongest family support networks can break down after a period where they feel they have nothing left to give emotionally to the affected person. It is critical that the role of the helping professional becomes one of enabler or facilitator, assisting people to regain control of their lives and to restore or improve their level of functioning.

The intervention model is built on a strengths-based approach (Brun and Rapp, 2001). Helping people to identify how they have coped with a difficult situation in the past can give them confidence to cope with the challenge of the current situation and to have a belief that they will get through or survive this experience. The strengths-based approach aids empowerment and recognizes the individual or community's ability to contribute to recovery. Social workers' knowledge of how groups and communities work is invaluable in understanding the dynamics, where the fractures might be, and where the strengths and social capacity might lie.

Ethical dilemmas are prevalent in this work. Confidentiality, for example, can be significantly compromised in the context of an evacuation center, a recovery center, or working out of a hotel or other tourist locale offshore. Providing services to affected Australians in other countries where local people do not receive the same level of support is ethically challenging. FST staff have been creative in devising ways of assisting local people.

Conclusion

Social workers in leadership positions in key Commonwealth and State government agencies influenced and shaped the policy and service delivery response in a catastrophic disaster. The Australian system of having social workers in the primary national service delivery agency made the responses illustrated in the case studies possible. Social workers made a significant contribution to building resilience and reconnection not just at the individual level but also at the family and the wider community level. Emergency response and recovery are complex, and there will always be criticism and aspects which could be improved or more appropriately responsive. These have been highlighted in the inevitable reviews and Royal Commission postdisaster. In my view, the Australian people's trust in government at various levels during emergencies has been greatly assisted by their response to the offshore disasters and the fires.

The social work profession has much to offer in emergency response. Mathbor (2007) makes the point that more needs to be done to include emergency work in social work curricula. Social work needs to claim legitimacy in this field. It needs to move beyond the clinical and direct service intervention to think more about strategic positioning. The opportunity to influence and shape the response and recovery effort can be challenging when many key players involved come from very different perspectives. They may be focused on physical, economic, and infrastructure aspects of recovery and do not necessarily have visibility of the social, emotional, psychological, cultural, and spiritual aspects. While these aspects are often covered within community recovery planning at all levels of government, they can sometimes appear to take a lesser priority. Bringing a focus to these matters at the strategic and operational level is a critically important role for social work.

Emergent Properties

Marlis Buchmann, University of Zurich, Zurich, Switzerland

This article is reproduced from the previous edition, volume 7, pp. 4424–4428, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

This article details varied concepts of emergent properties, including their relationship to systems theories. After reviewing the historical background of these concepts, the article focuses on the sociological tradition of emergence and then on more recent perspectives. Finally, methodological issues concerning emergent properties are discussed, such as the problem of their measurement.

The concept of emergent properties is the key element of a theoretical and methodological tradition claiming that the whole is more than the sum of its parts. This implies that the properties of a whole (systemic qualities) cannot be deduced by summing or averaging the properties of its components. Emergence theories are most elaborate in philosophical thought. However, an influential strand of twentieth-century social theory (Emile Durkheim, Talcott Parsons, Niklas Luhmann) borrowed some elements of this philosophical tradition and adopted the idea that the social (i.e., social organization at any level) should be regarded as an emergent property. By asserting that society is a reality of its own, nonreducible to the rules governing individual behavior, this sociological tradition stands in stark opposition to microreductionist thought. More recent approaches to the understanding of emergent properties (e.g., theories of self-organization and self-referentiality; chaos theory) are interdisciplinary in character, addressing research questions that allude to problems raised in classic emergence theory. However, the concept of emergent properties is used less as an analytical tool and more as a guiding research idea. In conclusion, methodological issues related to the measurement and the inference of emergent properties are discussed.

Emergence and emergent properties are concepts that are used across many scientific disciplines. They are the key elements of a theoretical and methodological tradition – most prominently represented in the 1920s – claiming that the whole is more than the sum of its parts. This amounts to saying that the properties of a whole (systemic qualities) cannot be deduced by summing or averaging the properties of its components (nondeducibility thesis). Vice versa, the appearance of genuinely novel properties characterizing compounds or systems as wholes (i.e., emergent properties) cannot be solely predicted from knowing the properties of the constituents and their relations. Emergence theories are most elaborate in philosophical thought. However, an influential strand of twentieth-century social theory (Emile Durkheim, Talcott Parsons, Niklas Luhmann) borrowed some elements of this philosophical tradition and adopted the idea that the social (i.e., social organization at any level) should be regarded as an emergent property. Arguing against the powerful approach of reductionism, this sociological tradition asserts that systemic properties of the social world cannot be deduced from properties of the constituents (i.e., individuals) and their respective interactions. They need to be accounted for at the system level. In the latter part of the twentieth century, the scientific discourse about emergence has regained prominence in many scientific disciplines – not to speak of a veritable renaissance. More recent approaches to the understanding of emergent properties include, among others, the theory of deterministic chaos, complex-system theory, and theories of self-organization and self-referentiality. Interdisciplinary in orientation, they focus on the complex dynamics between interactions and relations at different organizational levels (multilevel analysis) and stress the coexistence of system concepts and constituent concepts in explaining composition outcomes. After a brief history of the concept in philosophical thought, the major theoretical discourses about emergence in the context of social theory will be discussed. Next, there is a brief discussion of the recent interdisciplinary approaches that incorporate the idea of emergence. Finally, methodological issues related to the measurement and the inference of emergent properties are discussed.

The Philosophical Tradition of Emergence

The concepts of emergence and emergent properties have a long philosophical tradition (see Stephan (1999) and Beckermann et al. (1992) for extensive reviews). Unanimously, the origins of the idea of emergence are attributed to John Stuart Mill (1974). Considered to be the classic source, Mill distinguished between two types of joint effect produced by the interplay of various causes (composition of causes). In the first type, the joint effect of several component causes is identical with the sum of the separate effects. With respect to the second type, the joint effect is heterogeneous to the separate causes. The properties of a system or a compound generated by the second type of joint effect were later to be labeled emergent. Offering an alternative to mechanism and vitalism, the 1920s may be regarded as the heyday of the philosophical tradition that grew out of Mill's fundamental insight.

It was in this decade that those later to become *classic* authors – Samuel Alexander, Conwy Lloyd Morgan, Charles Broad, and Roy Sellars – published their influential works. According to Stephan (1999), 'weak' versions of emergentism may be distinguished from 'strong' ones. The former loosen some of the assumptions deemed to be essential for defining emergent properties in the latter versions. Both strands of

theory assert that emergent characteristics of wholes are not the sum of the properties of their parts (nonadditivity). They cannot be understood by simply summing (or averaging) the behaviors of the constituents; rather, they must be described in terms of their own. The novelty thesis claims that in evolution, genuinely novel (systemic) properties emerge. Examples are the advent of mind or reflective thought. In more abstract terms, this amounts to saying that emergent system properties are different in type from the properties of the system's constituent components. The two strands differ, however, with regard to the core assumptions of emergence theory – deducibility and predictability of systemic properties. Strong versions maintain that emergent properties are not deducible or predictable from the properties of the constituents and their relations (nonpredictability and nondeducibility). In this view, emergence may be characterized as the antithesis of microreductionism (Auyang, 1998). By contrast, in weak variants of emergence theory, all systemic properties that distinguish a system from the qualities characterizing its elements must be regarded as candidates for representing emergent properties. The late-1960s and early 1970s saw a renaissance of ideas of emergence. Centering on the fundamental issue of the mind–brain relationship – the psycho–physical problem – Bunge (1977) and Popper and Eccles (1977) offered theories strongly drawing on the idea of emergent properties.

Sociological Conceptualizations of Social Reality

From its inception, sociological thought has been characterized by two dramatically different conceptualizations of social reality. In particular, these differences pertain to the fundamental understanding of the relationship between the individual and social organization. Methodologically, this problem may be couched in terms of the relation between the micro- and macrolevels – in other words, the micro–macro link. One tradition, most commonly referred to as the individualistic–reductionist position, asserts that the properties of the social at any level may ultimately be explained by the interplay between the properties of individuals (e.g., motives, preferences), who are the constituents of society. Having strong roots in the Scottish moral philosophers (David Hume, Adam Smith, Adam Ferguson), the development of twentieth-century social theory has been characterized by various attempts to explain social phenomena by the rules governing the behavior of individuals. Basically, this approach asserts that social organization results from individual actions. Fundamentally opposed to this view is the other sociological tradition, often classified as the collectivist position. Its basic assumption is that the social world constitutes a reality of its own. Historically, this position is closely intertwined with the demands of sociology as a young scientific discipline to claim its territory and to define its own true subject matter vis-à-vis already well-established disciplines. By asserting that society is a reality of its own, nonreducible to the rules governing individual behavior, sociology distinguishes itself especially from economics and psychology. Searching for the particular subject matter of sociology, proponents of this position asked about the novel qualities and the specificity of the social vis-à-vis other types of reality, such as the mental realm, the biological or physical realm. It is with this latter tradition in sociology that the ideas of emergence and emergent properties have been most commonly associated. For this reason, the historical development of the latter tradition is discussed below.

The Sociological Tradition of Emergence: Society as an Emergent Property

In late-nineteenth and early twentieth-century sociology, the ideas of emergent properties are reflected in the conceptualization of society as representing a reality of its own endowed with separate characteristics nonreducible to the properties of its constituents (i.e., individuals). The sociological tradition that incorporates this assumption strongly draws on the thesis of emergence as nondeducibility (Bausch, 2001). In the early days of sociology, Emile Durkheim (1938) most prominently advocated this approach to the understanding of social phenomena. In Durkheim's view, society is not solely the sum of individuals; rather, it is the *association* of individuals. Hence, it is the *nature of this association* that constitutes the decisive factors of social life and determines the proper characteristics of social phenomena ('faits sociaux'). This theoretical stance was epitomized in the famous methodological rules introduced by Durkheim (1938) according to which the social realm needs to be explained by social phenomena.

In modern sociological thought, developed in the second half of the twentieth century, general systems theory has advanced to one of the most influential currents, implicitly or explicitly advocating ideas of emergence (Parsons, 1937, 1951; Luhmann, 1995). With the Durkheimian tradition, systems theory shares the fundamental methodological conviction of the nondeducibility of the social world. Social phenomena at different levels of social organization (i.e., society, organizations, social groups) show novel properties that cannot be explained by reducing them to the properties of and interactions between their constituents (i.e., behavioral properties of individuals). Hence, a genuine *social* theory is needed to account for social reality as an emergent property.

This line of thought, advocated by Durkheim in late-nineteenth-century sociology, was continued in the mid-twentieth century by Talcott Parsons, albeit with some major modifications (Parsons, 1951). For Parsons, the old problem raised by Hobbes about the origin of social order and social integration constitutes the fundamental sociological issue to which social theory needs to provide a satisfactory answer. The core of Parsons' answer to this fundamental problem is his thesis on the independence of institutionalized values and norms vis-à-vis the reality of individuals. The common system of ultimate values, constituting a reality *sui generis*, helps to establish order at various levels of social life and to prevent a free-for-all. In essence, Parsons declares common-value integration as the emergent property of social action systems. Parsons derives this conclusion from his systems-theoretical approach to the relationship between individual actors and social organization, whereby the starting point is the assumption that all reality realms constitute systems (i.e., the biophysical, personality, cultural, and social systems). Despite fundamental differences between various types of systems, they all share the system character as a common feature. By drawing a sharp distinction

between the social system (the social reality) and the personality system (the human being), Parsons maintains that each system needs to solve its own particular functional problem (i.e., system stability), for which each system relies on self-regulating mechanisms. In the case of the social system, social order and social integration are the functional problems, and processes of socialization and social control are the self-regulating mechanisms. Despite their own system logics, the two systems interact with each other in such a way that each system constitutes the environment for the other. The interactions between systems and their environment include the mutual exchange of resources, necessary for each system to keep up its functional capacity (i.e., system maintenance). Within this systems-theoretical framework, the social system and the personality system mutually presuppose each other; they are of equivalent status. This implies that there is no ontological priority of one system over the other. Hence, the properties of the social world cannot be deduced from the rules governing the personality system. The society is thus an emergent property.

Within the tradition of systems theory, Niklas Luhmann (1995) has provided the latest elaborate attempt to conceive of social reality as a separate, nonreducible system, reproducing itself solely on the basis of its own elements. Sharing some common ground with Parsons' theoretical approach, Luhmann designs a systems theory that makes use of fundamental ideas developed in molecular biology. In particular, Luhmann applies the concept of autopoiesis advocated by Maturana to social reality. Arguing at a very high level of abstraction, social systems are autopoietic systems in as much as they are self-reproduced by their own components, which are defined as acts of communication. This amounts to saying that social systems operate on the basis of communicative acts engendering subsequent acts of communication. Hence, the social system is an independent, self-reproductive whole. Like Parsons' theory, Luhmann's approach attributes great significance to the strict distinction between the social system and the psychological system. These two separate systems reciprocally constitute the environment of the other, for any system needs appropriate environmental relations for its self-reproduction. Given the system–environment relationship, the autopoiesis of the social system is not conceivable without the autopoiesis of the psychological system and vice versa. In other words, the two autopoietic systems enable each other to operate. From this it follows that the two systems are equivalent (and not hierarchically dependent), which precludes the reductionist assumption that systemic properties of one system can be deduced from those of any other system. Consequently, social systems are emergent properties.

The Renaissance of Ideas of Emergence in Late-Twentieth-Century Theoretical Thought

In the latter part of the twentieth century, ideas of emergence have again attracted considerable attention in various scientific fields. Several new approaches, such as synergetics (Haken, 1978) and other versions of self-organization theory (Krohn and Küppers, 1992; Krohn et al., 1990; Conte et al., 2001) or chaos theory (Newman, 1996), address interdisciplinary research questions at a relatively high level of abstraction that allude to problems raised in classical emergence theory. Examples of these research problems are the investigation of the spontaneous and self-confined emergence of new structures and systemic properties or the examination of predictability in chaotic dynamic processes. Interestingly enough, this body of research seldom refers to the tradition of emergence theory, and the notion of emergence itself remains rather vague. This suggests that, for these theoretical approaches, the concept of emergent properties is used less as an analytical research tool and more as a guiding research idea.

This is most apparent in the booming field of theories of self-organization. Krohn and Küppers (1992), for example, provide a rather vague concept of emergent properties. They define emergence as the sudden appearance of novel properties that can be explained neither by the properties themselves nor by the relations of the elements involved, but rather by specific self-organizing process dynamics. To complicate matters, the notion of self-organization is also a shifting concept. Depending upon the strand of system theory, the meaning attributed to self-organization turns out to be completely different. Searching for the least common denominator, self-organization may be understood as interactions between the components of a system and its organization that lead to modifications on both sides (Hejl, 1990: 115). It follows that the dynamics of self-organization engender new structures endowed with emergent systemic properties. In theories of self-organization then, self-referential organization of systems and emergent properties are causally related. Within this theoretical framework, social phenomena, such as social networks and social movements, easily lend themselves to the conceptualization of emergent properties generated by self-organizing process dynamics.

The issues addressed in theories of self-organization discussed above may be generalized to include the problem of how to conceive of the relationship between microinteractions and macrostructures – in short, the micro–macro link. With respect to social theory, the great bulk of previous work adheres to either a bottom-up method (microreductionism) or a top-down method (systems theory). Both methods, taken by themselves, have their limits. The reductionist tradition in social theory must at least acknowledge systemic properties as marginal conditions of individual behavior. Vice versa, the collectivist tradition is often short of explaining many systemic properties. Against this background, the need for a circular movement of theory building when conceptualizing the micro–macro link (i.e., interlevel explanations) is evident (Sawyer, 2003; Raub et al., 2011). Hence, approaches that attempt to couple systems concepts with constituent concepts are in demand. A theoretical framework of this type "simultaneously accounts for the behaviors of systems on one organizational level, the behaviors of their constituents on a lower level, and the relations between them" (Auyang, 1998: 5). In this respect, the approach of synthetic microanalysis proposed by Auyang (1998) may be regarded as one example.

Emergent Properties: Methodological Issues

Methodologically, the question arises of how to assess emergent properties. The key to answering this question lies in the

exploration of the link between the micro- and macrolevels of social phenomena. From this perspective, the claim that the whole is more than the sum of its parts amounts, first, to furnishing proof of the *specific assumptions* implied in either the 'strong' or 'weak' versions of emergence theory (see Section The Philosophical Tradition of Emergence). According to the 'strong' version, properties at the higher levels of aggregation (i.e., the macrolevel) qualify as emergent, if they *cannot* be deduced or predicted from the properties of units at lower levels (i.e., the microlevel). In the 'weak' version, they qualify, as long as they can be expressed as complex functions of the lower-level characteristics. Second, the assessment of emergent properties must be based on evidence regarding the *impact* of system properties (i.e., contextual properties) on lower-level units and/or relationships that operate independently of the effects of any lower-level characteristics. Couched in more technical terms, the second requirement implies that the attributes of units operating at the microlevel are a function of context (i.e., the macrolevel). The two tasks identified here to assess emergent properties address a measurement issue on the one hand and an issue about modeling techniques on the other. Each issue will be addressed in turn.

The Measurement Issue

'Strong' and 'weak' versions of emergence theory agree that higher-level properties that can be expressed as simple functions of lower-level attributes do not qualify as emergent. Examples include contextual characteristics defined as the sum, as a proportion, or as the mean of lower-level properties (e.g., percentage of community residents above the age of 65 years; average income of regions). The two strands of emergence theory differ, however, with regard to the theses of deducibility and predictability. The 'strong' version claims that emergent properties are *global* attributes that are not expressible as functions of lower-level properties. This implies that system properties need to be measured at the system level as opposed to the level of system elements. One example of such an approach would be the description of political systems characterized by the degree of corporatism, whereby the measurement of corporatism would be based on expert judgment.

The measurement issue involved in 'weak' versions of emergence theory includes the application of complex rules of aggregation. Expressed as complex functions of lower-level attributes, system properties can be deduced or predicted from lower-level units. The income distribution characteristic of regional contexts – expressed by a complex function of individual incomes – serves as an example. A methodological perspective that is well suited to identifying emergent properties in line with 'weak' versions of emergence theory is *network analysis*, most prominently advocated by scholars such as Ronald S. Burt, Mark Granovetter, and Barry Wellmann. This technique truly addresses the fundamental idea of the whole being more than the sum of its parts by focusing on *relational* characteristics and by introducing complex rules of aggregation. The social closure of elites, for example, cannot be inferred from the attributes of individual members of the elite. It is a property inferred from the *relational* attributes of the network members. Hence, the relational order of network elements (i.e., the structure) is a system property that truly qualifies as an emergent property. The second basic assumption of network analysis is the embeddedness of lower-level units in higher-level systems (i.e., networks) (see Granovetter, 1985). This implies that lower-level outcomes (e.g., preferences, tastes, action orientations, performance at the individual level) are mediated by higher-level system properties. This is to say that individual and collective actors respond to their social context. Couched in more technical terms, the notion of embeddedness addresses the issue of the additive and interactive effects of context on lower-level outcomes. This remark leads up to the second issue raised above, namely the modeling techniques required to assess emergent relationships.

The Impact Issue

To assess the effects of system properties measured at various levels of a hierarchical structure on lower-level outcomes, multilevel models (or contextual models) are the method of choice. A variety of models are used to specify the link between the macro- and microlevels of social phenomena. While the names of the models and their statistical properties do differ (e.g., hierarchical linear model, random coefficients model, hierarchical mixed linear model), the basic idea is "to analyze data that consist of multiple macro units (contexts) and multiple micro units within each macro unit" (DiPrete and Forristal, 1994: 334). Within these models, two types of effect can be distinguished: main or additive effects and interactive effects. Main effects of higher-level properties on lower-level outcomes (e.g., behavior) provide evidence that context matters over and above the impact of any lower-level attributes. This indicates that the relationships identified through the effect analysis cannot be reduced to individual differences. Examples of substantive research along these lines include the contextual effects of schools and classes on student achievement or the impact of macrocontexts, such as organizational structure and labor market segmentation, on career outcomes. The second type of effect involves interaction effects of properties measured at various levels of a hierarchical structure. The existence of cross-level interaction effects provides evidence of how higher-level properties (i.e., the macrocontext) affect the impact of lower-level attributes (i.e., those at the microlevel) on the outcome of interest. Variation in the strength of the effect of microlevel properties on the outcome when system properties are included indicates the presence of relationships that can be qualified as emergent. The reason is that interaction effects involving cross-level components show that they are more than the sum of their parts. Substantive research employing this complex modeling strategy includes, for example, the ways in which country characteristics (e.g., economic development; policy programs) affect the influence of maternal education on the reproductive behavior of women.

Emotional Development, Effects of Parenting and Family Structure on

Suzanne Bester and Marlize Malan-Van Rooyen, University of Pretoria, Pretoria, South Africa

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article's primary objective is to review the literature on the effects of parenting and family structure on the emotional development of children. Parenting styles play an important role in how children are socialized into society and it determines children's emotional, social, cognitive, and behavioral development. Parents are the most significant role players who determine the family environment which will directly influence their children's emotional development. In the twenty-first century there are many definitions of what constitutes a family. In this article, we will review traditional, divorced, single, step, adoptive, extended, and gay and lesbian family structures and how each one of these very different family structures influence children's emotional development. Specific attention will be given to risk and resilience factors which give each one of the aforementioned family structures a unique identity.

Introduction

Having children and raising them is part of our existence as human beings. Apart from ensuring the continuation of the human race, the act of becoming a parent and raising a child also has existential significance for many people. The profound experience of creating a life and taking on the responsibility of caring for and nurturing a child who will one day become living proof of their legacy motivates and drives many parents to commit fully to parenting their offspring. Parenting takes place in the context of a specific family structure where children are helped to achieve important social skills and developmental goals. In this context, parents play a key role in raising children to become emotionally competent and functional members of society. The individual characteristics of the particular child, parents, family, and society culminate in a context-specific, unique, dynamic, and varying experience for each parent and child.

Parenting and the Emotional Development of Children

Meaningful relationships are important in the parenting process as they help children develop emotionally and cope with problems. A parent–child relationship characterized by engagement, warmth, security, consistency, and appropriate parental responses is key to a child's emotional development (Walsh, 2012; Vélez et al., 2011; Brown, 2010; Stack et al., 2010; Fiese and Winter, 2009).

The parents' relationship often affects their parenting abilities. Parents who are aware of one another's needs, who support one another, and who display fondness and mutual respect are likely to handle the demands of parenthood with relative ease. Conversely, conflict between parents is likely to affect the parent–child relationship adversely often leading to emotional problems in the child. Ideally, parents should share responsibilities in a supportive and complementary manner (Driver et al., 2012; Waldfogel et al., 2010; Fiese and Winter, 2009; Schwartz and Finley, 2009).

By structuring a child's environment, a parent protects the child from negative environmental influences and creates positive influences. Parental knowledge is parents' knowledge of their child; knowledge of where their child is; knowledge of what their child is doing, and knowledge of how their child is coping with life (Padilla-Walker et al., 2011; Neumann et al., 2010).

Parental knowledge is considered one of the strongest protective factors against negative environmental influences. Sources of parental knowledge include child disclosure (children informing parents), parental socialization (parents questioning their child and their child's friends), and parental control (controlling where their child goes and what he (The feminine and masculine pronouns (she, he, her, him, hers, his) should be regarded as interchangeable in this article.) does) (Racz and McMahon, 2011; Padilla-Walker et al., 2011).

A warm and accepting parent–child relationship contributes to higher levels of parental control because it increases access to parental knowledge resources such as child disclosure and parental solicitation. Lower levels of parental knowledge can often be linked to inadequate family processes (Padilla-Walker et al., 2011; Bumpus and Rodgers, 2009).

A structured environment promotes feelings of self-efficacy in children and the ability to control their surroundings. Risk factors for children include economic instability and inconsistent parenting. Routines that foster emotionally and physically safer environments promote child well-being (Brown, 2010; Fiese and Winter, 2009). Abbott (2011) maintains that positive family structures can promote healthy child development. Protection from harmful environmental factors includes exposing the child to a nurturing, safe, and stable environment.

A safe and stable environment has social and physical components and is created by responding to the child's physical, developmental, and emotional needs. The family's role is to protect the child from physical harm and to create a stable environment characterized by consistency and predictability (Mercy and Saul, 2009).

Negative transitions or events (such as divorce, illness, or death) can undermine the process of providing a child with a nurturing, safe, and stable environment. Families need to be able to adapt to these transitions by making optimal use of resources such as positive relationships (i.e., positive parent–child and parental relationships); awareness of the child's interaction with the environment (i.e., parental

knowledge); and structuring of the family environment (i.e., economic resources, social resources, and routines) (Walsh, 2012).

The importance of the continuity of parental influence is self-evident, yet other factors and variables also contribute to the child's functioning. A bioecological systems perspective (Bronfenbrenner, 1979) holds that the individual characteristics of a child and her parents (e.g., temperament, cognition, biology) and the broader societal influences (e.g., culture, community), all contribute to a holistic picture of the child as an individual. Cummings et al. (2000) stress the importance of an integrative biopsychosocial approach in understanding parenting.

Brooks (2008a) identifies three major influences on the parenting process: the child's personal characteristics; the parents' personal history, psychological characteristics, and resources; and the social context of stressors and supports.

Parenting Styles and the Emotional Development of Children

Parenting styles refers to the 'how' of parenting, that is, how parents interact, discipline, communicate, and respond to the behavior of a child while socializing the child into their group. Baumrind (1991) originally identified two main parenting dimensions, namely acceptance/responsiveness and demandingness/control. These two dimensions are still the subject of much discussion (Rinaldi and Howe, 2012).

Berns (2007c) maintains that parents who are accepting of and responsive to their children tend to give them affection, provide encouragement, and show sensitivity to their needs. Conversely, parents who are unaccepting of and unresponsive to their children tend to reject them, to criticize them, and to be insensitive to their needs. Parents who are demanding and controlling tend to set rules and monitor their children's behavior, while parents who are undemanding and controlling tend to allow their children more autonomy and to make fewer demands on them. Uninvolved parents are neither responsive nor demanding. Four parenting styles emerge from these two dimensions: authoritative, authoritarian, permissive, and uninvolved.

Authoritative parents know how to place demands on their children and how to maintain control that is appropriate for their children's age. They are affectionate, communicate clearly, and respond appropriately to the needs of their children. They know how to balance demandingness and responsiveness. They also set clear standards for and monitor their children's behavior effectively (Alegre, 2011).

The authoritative parent–child relationship is characterized by warmth and monitoring resulting in generally higher levels of self-competence, self-esteem, social competence, and academic success in their children. It is also reported that lower levels of internalizing (e.g., depression, withdrawal, anxiety, somatization) and externalizing behaviors (e.g., aggression, attention problems, hyperactivity) occur in these children. Warm and supportive parents are regarded as good resources for their children that lead to positive developmental outcomes (Camp, 2012; Rinaldi and Howe, 2012).

Parent–child relationships characterized by warmth are also related to higher levels of emotional sensitivity, perspective taking (i.e., being aware of and understanding other people's situations), and prosocial behaviors (i.e., sharing and donating resources, comforting others, volunteering for charitable activities, and helping the needy) (Carlo et al., 2010).

Children of authoritative parents tend to outscore children from the other three parenting styles on measures of adjustment, attachment, resilience, school achievement, social and school competence, and prosocial behavior (Alegre, 2012).

Authoritarian parents expect their children to be obedient and not to question or challenge their authority. They are status driven, demanding, and often unresponsive to the needs of their children. Communication between these parents and their children is generally limited (Camp, 2012).

Authoritarian parents are strict and controlling. This, together with the high demands they place on their children, may result in behavior outcomes characterized by high levels of anger and self-centeredness. Disciplinary practices such as verbal scolding and physical punishment often also lead to aggressive tendencies and antisocial behavior (Camp, 2012).

Parental demandingness is a complex phenomenon marked by positive as well as negative responsiveness. Positive responsiveness includes monitoring and supervision, control, autonomy granting, making/having age appropriate demands, and expectations, and applying inductive discipline. This is often associated with higher academic functioning, life satisfaction, confidence, and prosocial behavior with less risk-taking behavior. Negative responsiveness includes psychological control and inconsistent, punitive and harsh discipline. The result is often higher internalizing and externalizing behaviors and cognitive anxiety with also a higher risk of personality disorders (Alegre, 2011).

Permissive and neglectful parents make few demands on and exercise little control over their children. Permissive parents are often responsive to and affectionate toward their children while neglectful or uninvolved parents often show little affection toward and rarely communicate with their children (Alegre, 2011).

The behavior outcomes of children with permissive parents seem to correlate strongly with poor self-reliance and self-control with a greater tendency toward impulsive and aggressive behavior and poor exploration behavior. The children of uninvolved parents tend to experience deficits in attachment, cognition, and emotional and social skills. They also often exhibit poor self-control and low self-esteem (Berns, 2007a).

Effect of Family Structure on Emotional Development

Traditional Families

Like other families, traditional families face risk factors that can compromise their ability to provide their children with a nurturing, safe, and secure environment. Most of these risk factors are also found in other family structures. These risk factors include difficulty in integrating work and family life, marital problems and conflict associated with preconceived ideas about gender role responsibilities (Fraenkel and Capstick, 2012; Brown, 2010; Kelly, 2010; Perrone et al., 2009).

A healthy marital relationship increases parents' well-being, confidence, and parenting skills. Marital problems can have

a negative effect on family functioning and specifically on children's social, emotional, and behavioral health. Marital problems are characterized by distressed spouses, negative and criticizing conversations, and disappointment in the relationship itself (Driver et al., 2012; Mannering et al., 2011; Brooks, 2008b). Children who are exposed to high conflict environments often present with emotional conditions such as depression, anxiety, and social withdrawal (Driver et al., 2012; Fraenkel and Capstick, 2012; Brooks, 2008b).

A common struggle in many families is integrating work and family life. Spending too much time and energy at work compromises a parents' ability to build quality familial relationships. Struggling to balance work and family life is also associated with higher levels of interpersonal conflict as well as lower levels of parental knowledge and monitoring (Fraenkel and Capstick, 2012).

Changes in gender role responsibilities have generally undermined parents' ability to balance family and work life. Traditionally, a women's role was being a full-time mother rather than a breadwinner. Changes in gender role responsibilities are linked to changes in work and family roles that can be beneficial in terms of financial resources but taxing in terms of role strain, which often leads to marital conflict (Perrone, 2009).

Various protective factors associated with traditional nuclear families can, however, help increase family resilience. When two parents are present in a family, certain requirements for improved child development can be met more easily such as more monitoring, more money, two role models, and a larger support network. Identity struggles are easier to avoid, and children have a wider variety of role models. If the parents are happily married, the children can generally experience a safer and more stable environment. Children in traditional families often have better education, employment, childbearing, and psychological outcomes making this still the optimal environment for the raising of children (Blau and Van der Klaauw, 2013; Abbott, 2011).

Divorced Families

The disruption and stress that accompanies unstable family processes before, during, and after divorce can lead to various behavioral, emotional, interpersonal, and academic problems in children. Stressors associated with divorce can compromise parenting abilities and often lead to irritability and impatience with the children (Amato, 2010; Berns, 2007b; Brooks, 2008b).

Risk factors that have an influence on the parent–child relationship during and after divorce include visitation arrangements; possible loss of a familiar neighborhood, school, and friends; reduced income; absence of a coparent; emotional stress and continuing parental conflict; as well as the possibility that the parents may become less emotionally available to the children during this process (Amato, 2010; Waldfogel et al., 2010; Schwartz and Finley, 2009; Brooks, 2008b).

Protective resources include effectively reorganizing the family structure by distributing responsibilities evenly, negotiating a workable relationship with the ex-spouse, and strengthening existing networks for support. If the parent–child relationship remains healthy, the negative impact of the divorce on the children's development will be ameliorated (Vélez et al., 2011; Amato, 2010; Odom et al., 2010).

Single Parent Families

Single parenthood can come about in various ways including the death of a parent, nonmarital births, and adoption (Anderson, 2012). Divorce is also considered a pathway to single parenthood, but since the existence of an ex-spouse often implies coparenting, it will not be discussed in this section.

Risk factors associated with single parent families include lower income, less time for the children, lower education, poorer neighborhoods, younger parents, less emotional support, and higher levels of child victimization, especially when the parent has a nonfamily cohabiting partner. In instances where the abovementioned risks are overwhelming, the children tend to present with emotional problems. These families often have fewer resources to meet the children's needs and to provide a safe, secure, and nurturing environment (Anderson, 2012; Falana et al., 2012; Huston and Bentley, 2010; Waldfogel et al., 2010; Turner et al., 2007).

The absence of one parent is often associated with less economic and socioemotional support. The economic hardship linked with single parenting can often impair parenting skills. Single parents frequently have either to work long hours or take on more than one job to provide additional income – this leads to less time investment in the parent–child relationship and accordingly affects the children's emotional well-being. Fulfilling the roles of two parents can result in role overload thereby impairing a single parent's parenting abilities and lowering her parental knowledge and monitoring (Brown, 2010; Padilla-Walker et al., 2011; Bumpus and Rodgers, 2009; Berns, 2007b).

Lower levels of parental knowledge could be attributable to less child disclosure and fewer solicitations. Parental knowledge, as mentioned earlier, can serve as protection against negative environmental factors. The provision of protection against such factors is a key role of parents (Bumpus and Rodgers, 2009).

Instability tends to be a characteristic of single parent families as such families often undergo more transitions than married parent families. Instability is manifested in frequent changes in the family structure (e.g., when a single mother's boyfriend lives with the family), and more frequent moving around can undermine existing social networks (Brown, 2010; Waldfogel et al., 2010; Turner et al., 2007).

Protective factors that can promote the resilience of a single parent mother include an involved father, an extended family, good socioeconomic status, psychological strength, and cultural support. A single parent can also extend her social network by joining community groups and faith congregations (Anderson, 2012; Walsh, 2012).

Stepfamilies/Remarried Families

Stepfamilies face numerous challenges inherent in adjusting to a new family life, which often leads to higher levels of conflict and instability. Challenges faced by stepfamilies generally revolve around complex familial relationships (Brown, 2010).

Ambiguous relationships, which are characteristic of stepfamilies, contribute to the complexity of such families making it difficult to foster sound relationships. The complexity of such relationships lies in redefining roles, questioning stepparents' authority, managing lower quality relationships, and increased levels of interpersonal conflict and deciding on the custodial rights of nonresident parents (Pasley and Garneau, 2012; Schrodt, 2011; Brown, 2010; Bumpus and Rodgers, 2009; Turner et al., 2007; Sweeney, 2010).

Research evidence indicates that the relationship between a stepparent and a child is more challenging than one between a biological parent and a child. Children often view the stepparent as an outsider leading to boundary ambiguity. The relationship between a child and a nonresident parent also becomes more complex after remarriage. The existence of an ex-spouse further complicates the relationship between the married couple. Negotiating parental roles and power and relational boundaries can lead to tension that can affect the quality of the couple's relationship. Endorsement of autonomy is a common problem, especially in respect of childrearing (Pasley and Garneau, 2012; Schrodt, 2011; Sweeney, 2010).

Stepfamilies often display lower parental knowledge than intact biological families. Parental knowledge, as mentioned earlier, is crucial in protecting children from negative environmental influences. Lower levels of parental knowledge can be attributed to lower level parent–child relationships and, accordingly, lower levels of solicitation of information (Racz and McMahon, 2011; Bumpus and Rodgers, 2009).

Despite the challenges facing stepfamilies, the existence of protective factors can help foster a more safe, stable, and nurturing environment. These factors include open communication, flexibility, realistic expectations, and being in tune with one another's experiences. Supportive coparenting between stepparents and nonresidential ex-spouses can help minimize the complexity of relationships and associated conflict. Effective readjustment of roles, especially in respect of childcare responsibilities, can enable a mother to spend more time with her children and thereby provide them with a further positive adult role model (Pasley and Garneau, 2012; Schrodt, 2011; Sweeney, 2010).

Extended Family – Kinship Care

Extended families consist of several generations of people and can include biological parents and their children as well as in-laws, grandparents, aunts, uncles, and cousins. Extended families are typical of collective cultures where all family members are interdependent and share family responsibilities including childrearing roles (Waites, 2009; Strong et al., 2008).

Extended family members usually live in the same residence where they pool resources and undertake familial responsibilities. Multigenerational bonds and greater resources increase the extended family's resiliency and ability to provide for the children's needs, yet several risk factors associated with extended families can decrease their well-being. Such risk factors include complex relationships, conflicting loyalties, and generational conflict (Engstrom, 2012; Waites, 2009).

Complex intergenerational relationships can complicate the child–parent relationship as they can cause confusion regarding the identity of the primary parent. Such confusion can result in a child undermining the authority of her existing parent (Anderson, 2012) and feeling uncertain about her environment.

Extended families often value the wider kin group more than individual relationships, which can lead to loyalty issues within the family and also cause difficulties in a couple's relationship where a close relationship between a husband and wife may be seen as a threat to the wider kin group. Another factor that can add to the complexity of relationships in an extended family is the need to negotiate the expectations and needs of each family member. Complex extended family relationships can also detract from the parent–child relationship (Strong et al., 2008; Langer and Ribarich, 2007).

The literature points to various protective factors associated with extended families that can help the parents and family meet the children's various needs. Extended families usually have more resources at their disposal that can be used to ensure the well-being of the children. Also, when the family functions as a collaborative team, has strong kinship bonds, is flexible in its roles, and relies on cultural values to sustain the family, the family itself serves as a lifelong buffer against stressful transitions (Engstrom, 2012; Waites, 2009).

Kinship care as a cultural value in extended families is associated with positive child outcomes, yet this may not be the case when such families have to take responsibility for a child because his parents are unable to do so. In such cases, kinship care becomes similar to foster care. Situations like the latter usually arise from substance abuse, incarceration, abuse, homelessness, family violence, illness, death, or military deployment (Langosch, 2012).

Although children in kinship care often fare better than children in foster care, various risk factors can have a negative impact on the children's well-being. Risk factors include low socioeconomic status, inability to meet children's needs properly, unhealthy family dynamics, older kin, less-educated kin, and single kin (Langosch, 2012; Palacios and Jiménez, 2009; Harris and Skyles, 2008; Metzger, 2008; Winokur et al., 2008).

Kinship care as foster care is often characterized by complex relationships and the trauma caused by the loss of an able parent. The family member who assumes the role as parent often finds it difficult to balance his former relationship with his new role as the person responsible for the child's well-being. For instance, a grandmother may have to adapt to the idea of being a strict parent instead of a loving, indulgent grandmother (Engstrom, 2012; Langosch, 2012).

The extended family member who steps into the parenting role is often overwhelmed by the stress caused by new parental responsibilities, attachment difficulties, and possible feelings of resentment and anger toward the biological parent, as well as having to deal with traumatic transitions after the loss of an able parent. The relationship between the new parent and other family members may also experience strain due to loyalty issues. Besides complex relationships, changes in the child's environment call for new routines, the setting of new limits, and sometimes coparenting with the biological parent, all of which can contribute to a less stable environment (Engstrom, 2012; Langosch, 2012).

An extended family member who takes on kinship care faces many challenges, although positive experiences associated with such care can also serve as a protective factor buffering the child against the negative effect of traumatic transitions. The new

parent may find this transition meaningful in the sense that it adds purpose to her life, and the child may also experience a sense of security, consistency, continuity in family identity, emotional ties, and familiarity (Langosch, 2012; Harris and Skyles, 2008; Metzger, 2008).

Adoptive Families

Adoptive families face all the challenges of contemporary nuclear families and more. Attachment difficulties are common among adoptive families and become even more challenging in cases where the adopted child was exposed to abuse or neglect. Adoption implies that the child will lose existing social and family structures, and frequent changes in caregivers and the loss of existing social networks can increase stress and anxiety in adopted children, making their environment seem unstable and unsafe (Carnes-Holt, 2012; Rampage et al., 2012).

Developing a safe and trusting relationship between the parents and an adopted child is challenging. Adoptive parents are often concerned about the quality of attachment that will develop between them and the adopted child. When children are adopted from institutions, such as orphanages, there is an increased possibility of disturbances in interpersonal relationships. Children who were exposed to abuse/neglect or anything that compromised initial attachment may need additional attention and care to foster sound attachment between them and the new parents. The challenges adoptive families face are often influenced by characteristics of the child such as age, race, and country of origin (Carnes-Holt, 2012; Garvin et al., 2012; Rampage et al., 2012; Tirella et al., 2012).

Adopted children whose race differs from that of their new parents may experience difficulties with their sense of ethnic identity. Parents who adopt from outside their own country may have limited access to information such as medical histories, prenatal care, and early living conditions. Racial and cultural differences may also compromise the parents' ability to provide relevant care, for instance, parents from a Western culture may promote independence while their child may be used to a culture that promotes interdependence. Children adopted within the first 12 months of their lives seem to have attachment relationships similar to those of nonadopted children, but older children often present more of a challenge (Carnes-Holt, 2012; Rampage et al., 2012; Docan-Morgan, 2010).

Protective factors that help adoptive parents build good attachments include strong parental relationships, thorough parental preparation, sharing responsibilities, and having a good support network. Structuring the environment on the basis of routine can help adopted children feel safe thereby also promoting attachment. Lastly, parents who encourage self-disclosure and provide emotional support facilitate the transition for their adopted children (Tirella et al., 2012; Docan-Morgan, 2010).

Lesbian and Gay Families

Lesbian and gay couples have various pathways to parenthood including having children from a former heterosexual relationship or marriage, adoption or conception through different reproductive technologies. Like heterosexual parents, lesbian and gay parents choose parenthood because of their desire to nurture a child, to be parents and to enjoy the company of a child. Lesbian and gay parents also face the same challenges as heterosexual parents such as balancing work and family life and adapting to parenthood. Challenges faced by lesbian and gay families generally stem from social prejudice, which can lead to victimization of the parents and their child (Green, 2012; Lee, 2009).

Within the parent–child relationship, the parents may need to pay special attention to issues such as social judgment, prejudice, and rejection that may affect the child. Social prejudice can undermine the child's identity since the child may not be regarded as an individual but simply as the "child of a lesbian or gay couple" (Rabitaille and Saint-Jacques, 2009: p. 436). This may even influence the child's interpersonal relationships as certain heterosexual parents may forbid their own children to play with the child. Children of lesbian and gay families consequently sometimes feel hesitant to share information about the nature of their family structure. Lesbian and gay parents should carefully explain this structure to their child within the safety of the parent–child relationship (Green, 2012; Lee, 2009).

Lesbian and gay couples also often face legal and social discrimination that may complicate their relationship, which is often 'sexualized' by society, meaning that society sees their relationship as exclusively sexual. Other aspects of the relationship such as love and commitment are often overlooked. Some lesbian and gay parents report downplaying their relationship in front of other role players in their child's life in an attempt to 'normalize' their parenting. Other relationship stressors include the logistics of starting a family, unsupportive laws, and the possibility of losing family and community support. Exposure to these stressors often impacts parenting skills negatively thereby also affecting the child (Lee, 2009; Wall, 2011).

Lesbian and gay parents are just as capable as their heterosexual counterparts of providing nurturing, safe, and stable family environments. However, they do face sexual prejudice that can turn judges, legislators, professionals, and the public against them often resulting in loss of physical custody, restrictions on visitations, and prohibitions against adoptions. Several countries and states have granted same-sex couples' rights, which include lesbian and gay marriages as well as adoption. Homophobia and discrimination, however, still affect lesbian and gay families. For instance, research reveals that these families still face discrimination when taking their children to healthcare services where they often experience parental exclusion and other difficulties with the health system due to their particular family structure (Amato, 2012; Chapman et al., 2012; Marks, 2012; Biblarz and Savci, 2010).

Despite the challenges faced by lesbian and gay families, various factors associated with lesbian and gay couples often act as buffers against stressful influences. Lesbian and gay couples tend, for example, to share domestic chores, decision-making, and parenting more equally than do heterosexual couples. Because of the shared roles, lesbian and gay couples often report higher satisfaction with their relationship and less socioeconomic stress. Additional social and community support also serve as valuable protective resources (Green, 2012; Berns, 2007b; Brooks, 2008b).

Conclusion

Much has been written about parenting and the role of the parent in the child's life, and much more will probably be written in the future. Parenting a child is a dynamic and ongoing process that shifts and changes together with changes in families across generations and changes in the environment and the broader society. We can never hope to understand fully the complexity of each individual family, but we can endeavor to peel away, discover, appreciate, and understand the multiple layers that constitute family life.

Emotional Intelligence and Competencies

Abstract

Emotional intelligence (EI) has been described as everything from a panacea to an invalid concept. This article focuses on recent research that clarifies what does and does not constitute EI, as well as its relationships with a variety of outcomes. We emphasize the role of EI in the workplace, and we distinguish between the positive outcomes that it facilitates, the negative outcomes to which it contributes, and the outcomes for which its role is unclear. We conclude by identifying specific issues that require further attention to advance our understanding of EI.

Emotional intelligence (EI) has a short but turbulent history. While it has risen to the heights of the cover of Time magazine, it has also been subjected to scathing criticism by its detractors. According to some, it is a panacea for industry's and society's ills. For others, it is an invalid concept. EI is a set of four interrelated abilities: the abilities to perceive emotions in the self and others, use emotions to facilitate performance, understand emotions and emotional knowledge, and regulate emotions in the self and others (Mayer and Salovey, 1997). The academic interest in EI started with the seminal work of Salovey and Mayer (1990). The widespread interest in it, however, is in large part the result of the popular books published by Goleman (1995, 1998). The argument that people could be intelligent in a way that is different from how 'smart' has commonly been understood seemed to have an intuitive appeal, and provocative claims about the importance of EI enhanced the appeal. For example, Goleman suggested that EI is twice as important as the combination of IQ and technical expertise with respect to the job performance of most employees (see Salopek, 1998).

The early research on EI, however, yielded mixed results, even the most positive of which failed to live up to the provocative claims. There were multiple definitions of EI, and many of them were inconsistent with one another. There were also multiple measures of EI, but a number of them overlapped with measures of extant constructs. The imprecise definition and measurement of EI made it difficult to assert that it was a separate, unique construct and to demonstrate that it could predict important outcomes above and beyond other well-known abilities (e.g., cognitive intelligence) and personality traits. This invited timely criticisms of the scientific status of emotional intelligence (e.g., Landy, 2005).

We review the recent research to clarify the definition of EI and the nature of its relationships with a variety of important outcomes, with an emphasis on its role in the workplace. We start with an overview of the three streams of research that ostensibly focus on EI. We then review the positive outcomes that it facilitates, the negative outcomes to which it contributes, and the outcomes for which its role is unclear. We conclude by identifying specific issues that warrant further attention, including cultural variance in EI, its differential impact for men and women, the training of EI, and measurement and methodological issues.

Row, Row, Row Your Boat, Gently Down the (First) Stream

There are three streams of research on 'emotional intelligence' (Ashkanasy and Daus, 2005), but just one of them captures a construct that can meaningfully use the moniker (Côté and Miners, 2006). It should be clear that any construct that purports to be EI should concern emotions *and* intelligence. It should also be clear that the construct should be measured in a way that captures what might reasonably be considered a form of intelligence.

Stream 1 is predicated on the work of Salovey and Mayer (1990). It conceptualizes EI as a set of four interrelated abilities: the abilities to perceive, use, understand, and manage emotions. Abilities reflect a person's capacity to successfully complete a particular task or, in other words, a person's maximum performance (Carroll, 1993). The way in which a person typically performs (i.e., across situations and over time) is the domain of personality traits, which are distinct from abilities (Sackett et al., 1988). Stream 1 therefore conceptualizes EI in a fashion that it is consistent with a form of intelligence.

Stream 1 employs performance tests to assess EI. Performance tests are comprised of questions, the answers to which are right or wrong, or more or less right or wrong. Intelligence concerns the capacity to solve problems (Neisser et al., 1996), hence it is important to employ measures that enable the identification of respondents who have a greater or lesser body of the relevant knowledge and a greater or lesser capacity to spontaneously solve relevant problems. Stream 1 employs omnibus measures of EI, the most popular of which is the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT; Mayer et al., 2002), and performance tests that are specific to a branch of EI (see Roberts et al., 2010 for a description of the measures). Recent meta-analyses have demonstrated that the MSCEIT has a positive correlation with measures of other forms of intelligence, and that it does not correlate highly with measures of personality traits (Joseph and Newman, 2010; O'Boyle et al., 2011).

Stream 2 also conceptualizes EI as a set of interrelated abilities, but it employs self- and peer-reports to assess it. The measures often ask respondents to indicate the extent to which they (or another focal individual) successfully engage in various behaviors. There are a number of problems with using

self-reports to assess a form of intelligence. The common thread among them is that people tend to make inaccurate estimates of their own abilities (e.g., Dunning et al., 2004). Peer-reports are also problematic for a number of reasons. For example, the respondents may not have observed the employee in a wide enough range of emotionally demanding situations to determine whether his or her behavior is the manifestation of one level of EI or another (Côté and Miners, 2006). For these reasons and others, it is difficult-cum-impossible to assert that Stream 2 captures EI. The results of a number of meta-analyses bolster this argument: the measures employed in Stream 2 do not correlate with the measures of other forms of intelligence, and they have a stronger correlation with measures of a number of personality traits (Joseph and Newman, 2010; O'Boyle, Jr. et al., 2011).

Stream 3 does not conceptualize EI as a set of interrelated abilities. Instead, it conceptualizes EI in terms of a series of behavioral outcomes. For example, Bar-On (1997) conceptualized EI as a set of noncognitive capabilities, competencies, and skills that concern (successfully) dealing with environmental pressures. Other researchers explicitly conceptualize it as a personality trait (e.g., Petrides and Furnham, 2001), resulting in the oxymoronic 'trait emotional intelligence.' All of the above conceptualizations incorporate elements that are not abilities and thus, by definition, cannot capture a form of intelligence. Stream 3 also relies on the use of self- and peer-reports. The results of the same meta-analyses and research, unsurprisingly, yield a similar pattern of results to those for the measures that are used in Stream 2: a relationship to other forms of intelligence that is conspicuous by its absence, and a relationship to personality traits that is conspicuous by its presence.

A review of the literature, therefore, shows that Stream 1 captures EI, whereas Streams 2 and 3 do not capture it. Streams 2 and 3 capture important, often highly predictive individual differences, but individual differences for which the moniker 'emotional intelligence' is inappropriate. We believe that the seemingly inauspicious start to research on EI was, at least in part, due to the use of multiple definitions and measures, a number of which were (and are) unfit for purpose. The remainder of this article focuses on Stream 1, and hereafter 'EI' should be understood as such.

The Good, The Bad, and The Ugly

The relationships between EI and a wide variety of important outcomes have been examined, ranging from the quality of social relationships to job performance. The strength of these relationships varies, and while EI is often beneficial (*The Good*), it can also be harmful to individuals and organizations (*The Bad*), or it can occupy an as of yet unclear role (*The Ugly*). Contrary to its (early) reputation as a panacea to organizational and societal problems, a high level of EI is not always the solution to a problem.

The Good

Interpersonal Relationships

EI facilitates interpersonal interactions, such that people with a high level of EI establish and maintain strong relationships. Expressions of emotion contain important information about (other) people's goals, attitudes, and intentions (Frijda and Mesquita, 1994). The abilities to decode emotional expressions, understand the impact of specific emotions on decision-making processes, and manage other people's emotions therefore provide an important means of anticipating and responding to other people in a socially appropriate manner (Côté et al., 2006).

Past research has shown that men with a high level of EI are more likely to be rated as socially competent by the people with whom they interact and by independent observers than men with a low level of EI (Brackett et al., 2006). Furthermore, men and women with a high level of emotion regulation, a branch of EI, are more likely to exercise interpersonal sensitivity and prosocial tendencies, and to be viewed in favorable terms by their peers (Lopes et al., 2005). Past research has also shown that the association between EI and the quality of social relationships remains intact, even when cognitive intelligence and the Big Five personality traits are entered into the analyses (Rossen and Kranzler, 2009).

Leadership Emergence

The same mechanisms that link EI to (positive) social relationships also help us to understand its relationship with leadership emergence. Leadership emergence is the degree to which a person who is not in a formal position of authority influences the other members of a group (Taggar et al., 1999). For example, if a person is able to decode (other) people's expressions of emotion, then he or she can determine their reactions to a proposed course of action. The ability to manage emotions, in turn, can help the person to change the other people's reactions if it becomes necessary to build further support for the proposed course of action (see Huy, 1999).

Recent research has shown that EI does, in fact, predict leadership emergence, even when controlling for cognitive intelligence and the Big Five personality traits (Côté et al., 2010). Walter et al. (2012) obtained a similar pattern of results. Their studies demonstrated that a branch of EI, emotion recognition, had a positive relationship with leadership emergence through its effects on task coordination, at least for people who also had a high level of extroversion. Recent research by Emery (2012) has shown that the abilities to perceive and manage emotions facilitate the emergence of relationship-oriented leaders, and that the abilities to use and understand emotions facilitate the emergence of task-oriented leaders.

Job Performance

The (positive) relationship of EI with job performance is likely to be a complex function of the indirect benefits of social capital and the direct benefits of successfully incorporating emotions in (or excluding them from) decision-making processes. EI should help employees to establish a high level of social capital that, in turn, will provide greater access to valuable information and other resources that facilitate job performance (Sparrowe et al., 2001). EI might also facilitate job performance more directly, by enabling employees to create or up-regulate the emotions that facilitate a particular task and down-regulate the emotions that interfere with it. A

person with a high level of EI is aware of the associations between emotion and cognition, and capable of changing the former to facilitate the latter. This, in short, will help the person to make the best possible decisions and help other people to do the same, which is likely to be reflected in their level of job performance (see Côté and Miners, 2006).

There are a number of individual studies and, now, meta-analyses that confirm EI can facilitate job performance. For example, with respect to the former, Kluemper et al. (2013) found that the ability to manage emotions can facilitate task performance and organizational citizenship behavior directed at the individual, and reduce the likelihood of workplace deviance. The pattern of results held even when a proxy for cognitive intelligence and a measure of the Big Five personality traits were entered into the analyses. The most recent meta-analysis was conducted by O'Boyle Jr. et al. (2011), who used dominance analyses to estimate the relative contributions of EI, cognitive intelligence, and the Big Five personality traits to job performance. They found that EI demonstrated substantial, relative importance even in the presence of these other, robust predictors.

Studies conducted by other researchers have shown that it may be helpful to consider the roles of other individual differences to understand the relationship between EI and job performance. Côté and Miners (2006) found that the relationship between EI and job performance becomes increasingly positive as cognitive intelligence decreases. EI, in other words, compensated for lower levels of cognitive intelligence in helping to achieve a high level of job performance. EI also interacts with other individual differences in a similar fashion, such that its role becomes more prominent if other means of achieving a high level of job performance are absent, or present but in an insufficient quantity. For example, Doucet and Oldham (2006) found that EI had a stronger relationship with job performance for employees at a telephone service center who possessed low levels of agreeableness and conscientiousness, both of which should facilitate a high level of job performance when present to a greater extent.

The results of recent research also suggest that the role of situational characteristics and job characteristics, in particular, should be considered to better understand the relationship between EI and job performance. For example, Farh et al. (2012) found that EI predicted job performance for employees whose work entailed a high level of managerial demands (i.e., the extent to which a particular job involves the management of diverse individuals, functions, and lines of business), but not for employees whose work entailed a low level of such demands. A meta-analysis by Joseph and Newman (2010) provides further impetus for considering situational characteristics. Their results showed that EI had a much stronger, positive correlation with job performance among jobs with a high level of emotional demands, at least when EI was conceptualized and measured as a set of abilities.

The Bad

Counterproductive Work Behavior

EI was presented as a panacea by some of its proponents. It can, however, be harmful to individuals, and it can be used to help other people or to harm them, depending on the ambitions of the particular person. There is now some research that seeks to redress the balance by presenting a more complete picture of the ways in which EI can be used. Elfenbein and Ambady (2002), for example, found that people who are skilled at recognizing emotions can be distracted by even low-level, subtle displays of negative emotion that should pass unnoticed. The distraction consumes resources (i.e., attention) that could otherwise be used on the task at hand, and performance suffers as a result of it. Côté et al. (2011) demonstrated that EI can be leveraged to increase people's level of prosocial behavior, *and* to facilitate deviant behavior that harms other people. Kilduff et al. (2010) have put forward an agenda for future research to examine the strategic deployment of EI or, in other words, to consider when it is used to advance personal interests, even at the expense of other people's success and well-being.

The Ugly

Negotiation

EI should facilitate creating and claiming value during negotiations (Fulmer and Barry, 2004). People with a high level of EI should be able to learn about a negotiation partner's preferences by decoding the information that the partner provides through his or her displays of emotion. Furthermore, they should be able to prevent strong, negative emotions from impacting the exchange of information, and to generate positive emotions that facilitate creative problem-solving, reciprocal positive actions, and frank discussion that will help both parties to move beyond positional bargaining (Adler et al., 1998; Kopelman et al., 2006). This should help to create value in negotiations. A high level of EI should also help people to generate or at least display emotions that beget concessions (and to hide emotions that require making them; e.g., Côté et al., 2013). A high level of EI should also help people to detect when a negotiation partner has reached the reservation point for a particular issue or set of issues (i.e., the lowest value that is still acceptable), and, therefore, to prevent unnecessary concessions (see Elfenbein et al., 2007). This should help to claim value in negotiations.

In spite of the above arguments, the evidence linking EI to negotiation outcomes is mixed. Elfenbein et al. (2007) found that the ability to perceive emotions helped dyads who completed the negotiation exercise to create more joint value (i.e., to increase the size of the outcomes that would ultimately be claimed by the individual members of the dyad). The same ability, however, helped the negotiators who occupied just one of the two roles in the exercise to claim value: the ability to perceive emotions facilitated claiming value for the participants in the role of seller but not in the role of buyer. Other research has focused on the subjective outcomes of negotiations. For example, Mueller and Curhan (2006) have shown that the negotiation partners of people with a high level of EI feel better about the negotiation outcomes, even after controlling for their positive affect and the objective outcomes that they claimed.

The above research suggests that EI may be of limited help with respect to claiming value in a negotiation, but it remains

unclear if and under what circumstances this is true. EI is, however, likely to be beneficial in other ways. For example, if a negotiation is a part of an ongoing relationship between two individuals, then its (positive) impact on the negotiation partner's perception of their outcomes may be invaluable (Elfenbein et al., 2007). A negotiation partner who is pleased with the outcomes that he or she has obtained, even if the reaction is unwarranted in objective terms, is more likely to be willing to negotiate again, and perhaps even to show a measure of generosity to help balance the previous 'successes' and nurture the relationship. Future research will elucidate the nature of the relationship between EI and negotiation outcomes, as additional studies are conducted and longitudinal designs are employed.

Leadership

A number of theoretical arguments link EI to desirable leader behaviors and leadership effectiveness. George (2000), for example, argued that EI should facilitate five core elements of leadership effectiveness, such as creating and maintaining enthusiasm, confidence, optimism, cooperation, and trust. Arguments about the role of emotional aperture in leadership (i.e., the ability to recognize the composition of diverse emotions in a collective) further suggest that the abilities associated with EI should facilitate organizational processes that can provoke strong emotions in employees (Sanchez-Burks and Huy, 2009).

There are, however, arguments to the contrary. Some have argued that a high level of EI will not contribute to leadership or, perhaps, that it might even work against it. For example, Antonakis has argued that condition-action scripts (i.e., mental if-then representations of how to behave in certain situations) are sufficient to explain effective leadership, and to prevent EI from usurping the explanatory power of cognitive intelligence and well-known personality traits (Antonakis et al., 2009). He further argued that a high level of the abilities that constitute EI, such as emotion recognition, may even be harmful, because they may result in unnecessary distraction and prevent leaders from making decisions that will benefit the organization, because even the best possible decisions are unlikely to please everyone.

The empirical research reflects this disagreement among various authors, and suggests that EI can but does not always predict leadership effectiveness. Rubin et al. (2005) showed that leaders with a high level of emotion recognition obtain higher ratings of transformational leadership from their employees than leaders with a relatively low level of this branch of EI, but only if they also had a high level of extroversion. Rosete and Ciarrochi (2005) found a positive relationship between EI and leadership effectiveness, indexed by 360° feedback about the achievement of organizational goals. In contrast, Føllesdal and Hagtvet (2013) found that none of the branches of EI or overall EI predicted employees' ratings of their leader's transformational behavior. A meta-analysis yielded a correlation of .24 in 10 studies that examined the relationship between EI and self-assessed transformational leadership, but the correlation dropped to .05 in the four studies in which subordinates rated the transformational leadership of their supervisors (Harms and Credé, 2010).

The connection between EI and leadership effectiveness is intuitive, but the empirical evidence that is currently available is sparse and not entirely supportive of the connection. As EI has multiple dimensions and leadership effectiveness can be indexed in more or less instrumental or affiliative terms, it will be interesting to clarify the role that EI plays in each domain of outcomes, and to explore any negative impact that it might have on leadership.

Discussion

The evidence reviewed in this article suggests that EI can be helpful to individuals and organizations. It also suggests that we should be wary of the bold claims made by some of its proponents. People should also be attentive to the ways in which EI can be harmful, and mindful of the fact that there are likely to be outcomes to which it does not contribute. EI appears to be beneficial to interpersonal relationships, leadership emergence, and job performance. EI, however, also appears to facilitate the achievement of less salubrious goals. It will be exciting to further explore its dark side and, in turn, to present a more balanced view of it that gives due attention to its virtues and its vices. The role of EI in other outcomes, including negotiations and leadership, if nothing else, requires further research. The current review is not meant to be exhaustive, but instead representative and suggestive of the broader literature. Even so, it is clear that Stream 1 could do with greater breadth and depth to fulfill its potential.

Future Directions

In this section, we discuss areas of research that have not yet received attention in this article or in previous reviews of literature (e.g., Côté, 2014). The main controversies raised in previous reviews relate to the definition and measurement of EI. As we have argued, we believe that future research should employ an ability model of EI and the corresponding performance tests. We now move beyond these issues to provide novel directions for future research.

Cultural Variability

Many of the current definitions and measures of EI have been developed in Western cultures, and thus reflect the values rooted in them. There is, however, a rich body of cross-cultural research shows that there is variability in the perception, expression, and regulation of emotions. For example, past research has shown that people from collectivistic cultures (e.g., Japan) value and encourage the open expression of emotions less than people from individualistic cultures (e.g., United States), because the expression of (negative) emotions can be detrimental to maintaining social harmony (Markus and Kitayama, 1991).

The lack of integration of culture into current models and measures of EI is problematic. For theory, it means that our current models of EI may not be correctly specified, and that the effects of EI on a range of organizational outcomes may be moderated by culture. For example, the consequences of poor emotion regulation may be more severe in collectivistic cultures that value emotion suppression than in individualistic cultures

that encourage the open expression of emotion. For practice, it means that a number of the available measures of EI may have an adverse impact on (potential) employees. If the current measures identify correct answers based on what is appropriate in Western cultures, then they may discriminate against non-Westerners. Indeed, research by Moon (2011) has shown that East Asians score lower on the MSCEIT than Westerners do, and that this effect was due, in part, to the incongruence between East Asians' preference for interdependence and answers that are based on the value of independence.

Given the theoretical and practical challenges of the current research on EI and the rapid globalization of the workplace, we encourage researchers to incorporate the role of culture into their investigations of EI. It would also be helpful to show a similar level of sensitivity to this issue as the next generation of measures is developed, so that researchers can explore the role of EI in a wider variety of cultures with confidence, and practitioners can reduce the likelihood of adverse impact.

Differential Impact for Men and Women

Discussion of the role of gender in the literature on EI has been sparse and, for the most part, focused on the variability in EI test scores that shows that women often score higher than men (see Joseph and Newman, 2010). A more substantive integration of gender into the research on EI is a curious omission, given that EI could be seen as a stereotypical feminine skill and, as such, it may have different consequences for men and women, especially in the workplace.

Past research on gender roles and stereotypes has shown that women are often expected to be warm, affectionate, empathetic, sensitive to others' needs, and good listeners (Eagly and Karau, 2002). Furthermore, it has shown that women who violate gender norms (i.e., who do not display stereotypical feminine traits) are punished (e.g., Rudman, 1998). There appears to be a substantial overlap between EI and stereotypical feminine traits, so it is possible (even probable) that women who do not display a high level of EI may be punished, whereas women who display a high level of EI may not gain very much (especially compared to men). In other words, possessing and displaying a high level of EI may not help to advance women's careers, but a low level of EI (or the failure to display a high level of EI) may hinder them.

This discussion also raises a question about men: would men who display a high level of EI be punished because they are violating the expectations that are associated with stereotypical masculine traits? Past research has shown that men and women incur penalties when they violate their respective gender roles (e.g., Rudman, 1998). Thus, if we construe EI as a feminine set of abilities, men who display a high level of EI may be more likely to be punished than men who display a low level of EI. At the same time, past research has shown that men who display stereotypical feminine traits (e.g., empathy) coupled with stereotypical masculine traits (e.g., ambition) are perceived favorably (Prentice and Carranza, 2002). In other words, a high level of EI may present a unique advantage for men who aspire for leadership positions.

We have outlined a number of possible ways in which EI might differentially influence the careers of women and men, and whether our specific conjectures are right or wrong, we believe that this issue warrants further investigation.

Training

There is a lot of interest in training EI in organizational and educational contexts, but the research on it has been sparse and inconclusive. Some past research suggests that branches of EI can be improved, such as emotion recognition (Elfenbein, 2006). Other research on developing EI, however, has used self- or peer-report measures of EI, rather than a performance test (e.g., Kotsou et al., 2011), hence it is difficult to attest to much more than an improvement in declarative knowledge. Other research still has questioned whether it is even possible to develop EI, especially if EI is defined as a form of intelligence (see Côté, 2014 for a discussion of the trainability and heritability of EI). Furthermore, even if EI can be developed, there is another problem that needs to be solved. Sheldon et al. (2014) found that the people who need the training the most are the least motivated to take it!

If one overlooks the (academic) debate about whether EI *itself* can be developed, then it appears to be possible to develop skills that help people to behave in ways that could be described as 'emotionally intelligent.' Returning to the debate in question, current research has not provided conclusive evidence that EI can, in fact, be trained. As such, we believe that more systematic research on this issue is warranted, particularly given that there is already a large demand for such services.

Measurement and Methodological Considerations

Our review, among other things, has outlined an agenda for advancing our understanding of EI. We would be remiss, however, not to outline some important methodological considerations that should be in place before the research is conducted. The first consideration relates to the measurement of EI. The MSCEIT is the most widely used and extensively validated performance test, but some important concerns have been raised regarding its psychometric properties and its scoring system (e.g., Conte, 2005). To this end, other measures of EI have been developed, and should also be given due consideration (see Roberts et al., 2010 for a review of the available measures).

Furthermore, most research on EI has focused on overall EI rather than on the effects of its specific branches. Past research, however, has shown that different branches may be more or less helpful (or harmful) in one situation or another (e.g., Elfenbein et al., 2007). Assessing overall EI therefore may provide an incomplete or even inaccurate picture of its role. We therefore encourage researchers to continue developing branch-specific hypotheses, and to be mindful not just of which individual branch(es) matter(s) the most, but also of the way in which configurations of multiple branches might affect various outcomes (e.g., a high score on perceiving emotions and a low score on managing emotions might be especially detrimental to an individual's job performance).

Conclusion

EI is popular, but its popularity has done at least as much harm as good. The unrealistically high expectations set by some of its proponents, ironically, were not and are not endorsed by the very people who introduced the concept (i.e., Salovey and Mayer; see Mayer, 2004). These expectations, coupled with the

inconclusive early research, resulted in criticism that was overly pessimistic. We hope that this article has found the middle ground, somewhere closer to the truth: EI can be beneficial to individuals and organizations, but it can also be harmful to them, and its role in a number of outcomes will only be clarified through further research.

Acknowledgments

We thank Stéphane Côté, Paulo N. Lopes, Amanda C. Kesek, and the Section Editor, Richard D. Roberts, for their advice and insightful comments on earlier drafts of this manuscript. This work was supported by two research grants from the Social Sciences and Humanities Research Council of Canada, one to the first author and one to the second author.

Abstract

Emotion regulation involves attempts to change the experience and expression of emotions. People engage in such attempts to satisfy either hedonic motives (i.e., to feel good in the moment) or instrumental motives (i.e., to effectively achieve their goals). To change their emotions, people can engage in a variety of strategies. While some strategies (e.g., cognitive reappraisal) have been found to be relatively effective, others (e.g., expressive suppression) have proven less effective. The quality and efficacy of emotion regulation depends, in part, on the mental resources people have at their disposal, on their beliefs about the ability to change emotions, and on their knowledge and understanding of emotions. The process of emotion regulation, in turn, carries important implications for subsequent emotional experiences, for cognition and decision-making, for social interactions, for mental and physical health, and for well-being.

Our daily life is imbued with emotions. Sometimes we savor them and sometimes we try to change them. Overcoming fear of public speaking, getting ourselves excited about a new project at work, stifling an inappropriate giggle – these are all examples of emotion regulation. Emotion regulation involves attempts to maintain, increase, or decrease the experience and expression of unpleasant or pleasant emotions (Gross, 1998). Intrinsic (or intrapersonal) emotion regulation involves attempts to change the experience or expression of our own emotions, whereas extrinsic (or interpersonal) emotion regulation involves attempts to change the experience or expression of emotions in others (Thompson, 1994).

Emotions are reactions to goal-relevant events that involve changes in subjective experience, which may be accompanied by changes in cognition, physiology, and behavior (*see* Emotions, Psychological Structure of). Given that emotions carry important implications, it is not surprising that emotion regulation has been implicated in important outcomes across multiple domains, including decision-making, organizational behavior, intergroup relations, education, psychological and physical health, and well-being (for recent reviews, see Gross, 2014).

Research on emotion regulation in the past few decades has addressed many key questions. These include why people regulate emotions, how people regulate emotions, what influences the way people regulate emotions, and whether and how emotion regulation influences subsequent outcomes. In what follows, we discuss each of these questions and review some of the research that speaks to them.

Why Do People Regulate Emotions?

People engage in emotion regulation for different reasons. To date, researchers have distinguished between two categories of motives that drive emotion regulation (e.g., Tamir, 2009) – namely, hedonic and instrumental. First, people regulate emotions to achieve hedonic benefits, that is, to increase pleasure and decrease pain (e.g., Larsen, 2000). Pleasant emotions, such as happiness or joy, feel good, whereas unpleasant emotions, such as fear, sadness, or anger, feel bad. By increasing pleasant emotions and decreasing unpleasant emotions, people can increase pleasure and decrease pain, respectively. Therefore, people are often motivated to increase pleasant emotions and decrease unpleasant ones to attain hedonic benefits.

Second, people regulate emotions to achieve instrumental benefits – namely, to increase utility or expected benefits (e.g., Tamir, 2009). Regardless of how pleasant they are, emotions can be useful or harmful for goal attainment. For instance, happiness is pleasant, but it may also promote successful collaboration. Similarly, anger may be unpleasant, but it may also promote successful confrontation, and fear may be unpleasant, but it may promote successful avoidance of threat (e.g., Frijda, 1986). Both pleasant and unpleasant emotions may be useful in certain contexts and harmful in others. By increasing useful emotions and decreasing harmful emotions, whether they are pleasant or unpleasant, people can increase utility (Parrott, 1993). Therefore, people are often motivated to increase useful emotions and decrease harmful emotions to attain instrumental benefits. Because emotions that are unpleasant may be useful in certain contexts, people may be motivated to experience even unpleasant emotions to promote the attainment of instrumental goals. For instance, people may be motivated to increase their anger in preparation for a fight (e.g., Tamir et al., 2008).

What people want to feel, in turn, determines the direction in which they regulate their emotions. People who are motivated to feel less angry will try to decrease their anger, whereas those who are motivated to feel angrier will try to increase their anger (Tamir et al., 2008). People who regulate their emotions to satisfy hedonic motives will likely try to increase positive emotions and decrease negative emotions. People who regulate their emotions to satisfy instrumental motives may try to change their emotions in whichever way they believe would promote the attainment of their goals (Tamir et al., 2014).

How Do People Regulate Their Emotions?

People can use various strategies to regulate their emotions. There have been two approaches to studying emotion-regulation strategies. One approach focuses on particular strategies, in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25055-1

an attempt to identify and understand their unique antecedents and consequences. A second approach focuses on broader theoretical models that organize multiple types of regulation strategies.

One prominent example of the first approach to studying emotion-regulation strategies involves research on rumination, which involves repetitively thinking about the symptoms of one's distress, and on its possible causes and consequences (Nolen-Hoeksema et al., 2008). For instance, after having failed a test, a person who ruminates might think about the test over and over again, focusing on how they have done wrong and how this might affect them. Although people might engage in rumination in an attempt to resolve negative events, rumination is ineffective in decreasing negative emotions (e.g., Webb et al., 2012), and may even backfire (Nolen-Hoeksema et al., 2008). Indeed, there is evidence that rumination can actively contribute to psychopathology, and depression, in particular (e.g., Aldao et al., 2010).

Perhaps the best example of the second approach to studying emotion-regulation strategies is research on the process model of emotion regulation (Gross, 1998). According to this model, emotions unfold in a sequence of four stages: situation, attention, appraisal, and response. First, we encounter an emotion-eliciting situation. For instance, after having had dinner with friends, we might find ourselves walking alone back to our car, which is parked in a dark alley. Second, we attend to the emotion-relevant features of the situation. For instance, our attention is drawn to a few large men huddling in a corner. Third, we assign meaning to the situation, through a process of cognitive appraisal. For instance, we might tell ourselves that this group of men could be dangerous. Finally, we have an emotional response. For instance, we might feel fear and hurry to our car as fast as we can.

According to Gross' process model, emotion regulation can be activated in different stages of the emotion-generation process. Emotion-regulation strategies, therefore, can be distinguished by the specific stage they target in the emotion-generation process (Gross, 1998). The first two types of strategies involve attempts to alter the situation that elicits the emotional response. First, situation-selection strategies are initiated before people encounter an emotion-eliciting event. Such strategies involve attempts to influence the likelihood of encountering events that elicit desired (or undesired) emotions. For instance, we could decide to take a cab to dinner earlier in the evening, thereby eliminating the need to walk alone in a dark alley at night – a situation that may elicit fear. Second, situation-modification strategies are initiated when people encounter an emotion-eliciting event. Such strategies involve attempts to change the nature of the situation itself in a manner that changes its emotional impact. For instance, we could ask some friends to walk us to our car after dinner, thereby increasing our sense of safety, making it less likely that we would feel fear. Situation selection and situation modification involve attempts to change the situation that elicits emotions.

The next two types of strategies involve attempts to change the way we process the emotion-eliciting event. First, attention-modification strategies are initiated after the encounter with the emotion-eliciting situation. These strategies involve attempts to redirect attention away or toward emotion-eliciting features of the situation. For instance, if we are bound to walk alone to our car at night, we could decide to focus our attention on the elderly couple walking hand in hand rather than the group of huddling men, keeping our fear at bay. Second, cognitive-change strategies are initiated after we have attended to the emotion-eliciting features of the situation. These strategies involve attempts to change our interpretation or the meaning we assign to the situation, so that the emotional impact of the situation changes. For instance, assuming we have already attended to the group of huddling men, we could tell ourselves that these men are not much different than the friends with whom we have had dinner, who are enjoying each other's company after a hard day at work. This interpretation makes the situation less threatening, making it less likely that we would feel fear.

According to Gross (1998), the strategies discussed above are antecedent-focused strategies, because they are initiated before the emotional response. Response-focused strategies are initiated after the emotional response has occurred and target features of the emotional response, including experiential, physiological, behavioral, and expressive features. For example, as we get scared watching the group of men huddling in the dark alley, we may try to hide the expression of fear on our faces and continue walking at a steady, calm pace toward our car.

Gross' process model gives rise to predictions regarding the relative efficacy of different regulation strategies. According to Gross (1998), antecedent-focused strategies should be more effective than response-focused strategies, because they are initiated earlier in the process. To test this prediction, researchers have focused on two specific regulation strategies – namely, cognitive reappraisal and expressive suppression (e.g., Gross, 1998). Cognitive reappraisal is an example of a cognitive-change strategy, which involves changing the appraisal of a situation. Expressive suppression is an example of a response-modulation strategy, which involves inhibiting the overt expression of emotion. There is now considerable evidence showing that cognitive reappraisal is relatively effective in changing emotional experience, whereas expressive suppression is relatively ineffective (Webb et al., 2012).

In addition to identifying specific emotion-regulation strategies and studying their relative efficacy, researchers have examined the manner in which regulation strategies are employed. Recent research on self-regulation, broadly construed, has demonstrated that although people often use conscious effort when using regulation strategies, they can also activate such strategies unconsciously (e.g., Mauss et al., 2007). For instance, participants who were implicitly primed with the concept of reappraisal were as effective in decreasing their physiological arousal as those who were explicitly instructed to reappraise (e.g., Williams et al., 2009). Although there is some evidence that people can regulate their emotions without conscious intention, there is still some debate about the nature, antecedents, and consequences of automatic emotion regulation.

What Are the Antecedents of Emotion Regulation?

In addition to why and how people regulate their emotions, there are various factors that influence whether and how successfully they do so. In this section, we review several key factors that influence the nature and efficacy of the emotion-regulation process. These include the regulatory resources that

enable people to regulate their emotions, people's beliefs about the feasibility of emotion regulation, and people's knowledge about emotions.

Ability

All forms of self-regulation require mental resources, and emotion regulation is no exception (*see* Self-Regulated Learning). There is evidence that emotion regulation can be depleting. Effortful emotion regulation impairs performance on subsequent effortful tasks, is impaired when the individual is placed under high cognitive load, and in individuals with impaired executive functioning skills (for a review, see Zelazo and Cunningham, 2007). Therefore, to regulate emotions effectively, individuals need to have sufficient regulatory resources.

Beliefs

To engage in emotion regulation, people need to believe that emotions can be controlled. People have implicit theories (i.e., beliefs about the malleability of attributes) about emotions (Tamir et al., 2007). Some people hold entity beliefs about emotions and believe that emotions cannot be controlled, whereas others hold incremental beliefs about emotions and believe that emotions can be controlled. The more people believe that emotions are controllable, the better they are in controlling their emotions and the more pleasant and the less unpleasant emotions they experience over time (Tamir et al., 2007).

To engage in emotion regulation, however, people must believe not only that emotions can be controlled, but that they personally are capable of regulating their emotions. Self-efficacy refers to the belief that one has the ability to exert control (*see* Self-Efficacy). People vary in their self-efficacy in emotion regulation. People who believe that emotions can be controlled experience more self-efficacy in emotion regulation, and this sense of personal efficacy is associated with the experience of more-pleasant and less-pleasant emotions and with more effective emotion regulation (Tamir et al., 2007). Therefore, to attempt emotion regulation people may need to believe that emotions can be controlled and that they personally can regulate their emotions.

Knowledge

To effectively regulate emotions, people need to know what emotions are, what gives rise to them, what their consequences are, and how they can be modified (Barrett and Gross, 2001). Individuals who have more elaborate knowledge about emotions are more effective at emotion regulation. For instance, people who were better able to differentiate between discrete emotional experiences reported using a wider range of regulation strategies (Tugade et al., 2004). Therefore, to regulate emotions effectively people need to know and understand emotions.

What Are the Consequences of Emotion Regulation?

Emotion regulation carries important implications in multiple domains. As might be expected, emotion regulation influences emotional experience. In addition, however, emotion regulation influences cognition and decision-making, social relationships, health, and well-being. We review each of these domains below.

Emotion Regulation Influences Emotion

People engage in emotion regulation in order to regulate their emotions. Indeed, emotion regulation can change the experience and expression of emotions. People who are trained and instructed to use effective regulation strategies are successful at reducing negative emotional reactions to distressing stimuli (see Webb et al., 2012). For example, cognitive reappraisal, distraction, and distancing are effective in decreasing negative emotional reactions. When emotion regulation is used effectively, it can change emotional experiences in both adults and in children (e.g., Thompson, 1994).

Emotion regulation can change not only the experience, but also the expression of emotions. For instance, expressive suppression involves decreasing the overt expression of emotions, whereas venting involves the overt expression of negative emotions. Both are effective ways of controlling the expression of emotions.

Emotion Regulation Influences Cognition

Some forms of emotion regulation carry cognitive costs (for a review, see Suri et al., 2013). For instance, certain strategies impair the processing of event-related information. In particular, distraction leads to more superficial processing of the emotion-eliciting event, because it involves intentionally diverting attention away from it. Expressive suppression also impairs memory of the emotion-eliciting event, potentially because of the mental resources it requires. Other forms of emotion regulation carry cognitive benefits (for a review, see Suri et al., 2013). For instance, there is evidence that some strategies (e.g., cognitive reappraisal) promote enhanced recall of explicit memory. Emotion regulation, more generally, could promote effective processing of information. For instance, children who were instructed to decrease their emotional responses were better able than others to recall educational material.

Emotion Regulation Influences Decision-Making

Some forms of emotion regulation may promote certain aspects of decision-making. For instance, emotion regulation may influence risk-perception. Participants who actively increased their anger became less aversive to losses, and consequently made riskier financial choices (e.g., Tamir et al., 2014). Emotion regulation can also influence utilitarian reasoning. When facing an unfair financial offer, people usually reject the offer and prefer to get nothing rather than agree to an unfair division. Participants who actively decreased their anger were more likely to accept an unfair offer to increase personal financial gain (Wout et al., 2010).

Emotion Regulation Influences Social Interactions

There is considerable evidence that emotion regulation influences social interactions, from intimate bonds to group

processes. First, emotion regulation plays an important role in close relationships (Shaver and Mikulincer, 2007). According to attachment theory, individuals are motivated to maintain proximity to attachment figures. When faced with potential separation, individuals experience distress and are motivated to reestablish proximity. This process initiates the regulation of emotion. Emotion regulation is recruited to deal with attachment threat. Securely attached individuals experience their distress, notice it, and tolerate it. Anxiously attached individuals engage in hyperactivation strategies, increasing the experience and expression of distress, to increase the chances that the attachment figure will attend to them. Avoidantly attached individuals engage in deactivating strategies, decreasing the experience and expression of distress, given that they view the attachment figure as nonresponsive (Shaver and Mikulincer, 2007). These regulation strategies are assumed to influence the nature and quality of close relationships.

Second, emotion regulation plays an important role in social relationships, more broadly. In particular, decreasing emotions that promote interpersonal violence (e.g., anger, hatred) can result in more adaptive social outcomes. There is evidence that aggressive behavior is associated with impaired emotion regulation. Children who have difficulties in regulating their emotions are less socially competent and behave more aggressively toward others. Similarly, adults who have difficulties regulating their emotions are more likely to be violent toward intimate partners. In contrast, effective emotion regulation is associated with more stable and positive relationships (for a review, see English et al., 2013).

Both the regulation of emotional experience and the regulation of emotional expression influence social relationships. For example, sharing emotions with other people not only improves one's ability to cope with negative events, but it also strengthens the social bond between the sharer and the person with whom she/he shares emotions (Rimé, 2007). While the expression of emotions to others carries social benefits, the suppression of emotional expression carries social costs. People who suppress the expression of their emotions are less effective in communicating with others, are liked less by others, and are perceived by others as inauthentic (see English et al., 2013). Suppression of emotions can also have deleterious effects in the workplace (e.g., Côté and Morgan, 2002).

Finally, emotion regulation plays an important role not only in dyadic relationships, but in group contexts as well (for a review, see Halperin, 2014). In the context of the Isreali–Palestinian conflict, Israeli participants who were trained to decrease their anger using cognitive reappraisal were more willing to provide humanitarian aid to Palestinians and less likely to support aggressive policies. Such studies demonstrate that emotion regulation can be used to enhance less-aggressive and more-peaceful social relationships, at the dyadic and group levels.

Emotion Regulation Influences Mental Health

Impairments in emotion regulation actively contribute to psychopathology. Difficulties in regulating negative emotions and the use of ineffective regulation strategies contribute to longer episodes of depression in depression-prone individuals (see Joormann and Siemer, 2014). Similarly, difficulties in regulating positive emotions seem to contribute to the development of mania in bipolar disorder (Gruber, 2011). More generally, dysfunctional emotion regulation has been implicated in depression, bipolar mood disorder, borderline personality disorder, generalized anxiety disorder, post-traumatic stress disorder (PTSD), substance-use disorders, eating disorders, and somatoform disorders (see Berking and Wupperman, 2012).

Emotion dysregulation in psychopathology may involve two possible factors. First, individuals who suffer from psychopathology tend to use ineffective regulation strategies (e.g., rumination, suppression) and fail to use more effective ones (e.g., reappraisal). Second, individuals who suffer from psychopathology have difficulties in using emotion regulation in a flexible and context-dependent manner (Bonanno and Burton, 2013). Instead, they are likely to use few regulation strategies in a rigid manner, regardless of what the situation calls for, thus impairing their success in regulation.

Emotion Regulation Influences Physical Health

There is some evidence linking emotion regulation to physical health. Using less-effective emotion-regulation strategies (e.g., suppression) has been associated with a greater risk of chronic health outcomes, such as heightened cortisol reactivity in response to stressors (Lam et al., 2009). In contrast, effective emotion regulation has been related to a lower risk of metabolic syndrome (Liukkonen et al., 2006). Similarly, writing about personally upsetting topics has been found to have beneficial influences on immune function, including t-helper cell growth, antibody response to Epstein–Barr virus, and antibody response to hepatitis B vaccinations (e.g., Pennebaker et al., 1988). Taken together, these findings suggest that emotion regulation impacts physical health. However, the mechanisms by which they do so remain to be examined.

Emotion Regulation May Influence Well-being

Emotions comprise an important component of well-being. Therefore, it is conceivable that the regulation of emotions can contribute to well-being (see Nyklicek et al., 2011). Individuals who can effectively regulate their emotions report higher levels of life satisfaction and psychological well-being, compared to those who do not engage in emotion regulation or regulate their unpleasant emotions ineffectively (e.g., John and Gross, 2007). Similarly, people who cultivate pleasant emotions are more satisfied with their lives and are less likely to suffer from depressive symptoms. Emotion regulation also mediates the effects of life stress on well-being. For instance, people who use cognitive reappraisal are more likely to recover from emotional stress and less likely to suffer from depressive symptoms (Troy et al., 2010). Much of the research linking emotion regulation to well-being is correlational, however, and whether emotion regulation influences well-being or well-being influences emotion regulation is yet to be determined.

Summary: Healthy Emotion Regulation

Emotion regulation is a process by which people change the experience or expression of their emotions. It can be used to

make people feel better or to achieve a variety of both personal and interpersonal goals. It can be accomplished using a variety of strategies, some more effective and some less effective than others. It is influenced by the regulatory resources people have at their disposal, by their beliefs about emotions, and by their knowledge of emotions. Finally, it impacts how people feel, how they think, how they make decisions, how they interact with one another, as well as their mental health, physical health, and well-being. To promote adaptive outcomes across these diverse domains, people need to engage in healthy emotion regulation.

Healthy emotion regulation involves changing emotions in a useful and context-sensitive manner. Healthy emotion regulation has several key features. First, it involves regulating emotions in a manner that is consistent with one's goals. Second, it involves using effective regulation strategies and avoids using ineffective ones. Third, to be healthy, emotion regulation should be used in a flexible, variable, and context-sensitive manner. Indeed, it is important to know not only when to regulate, but also when not to regulate and instead embrace emotional experiences as they are (Hayes et al., 2006).

Emotion and Expression

Abstract

The scientific study of emotional expression began with studies of facial expression in the nineteenth century. Studying these expressions has been an important site for disputes over the existence of a universal human nature and disputes about whether emotions are naturally divided into a manageable number of discrete kinds with innate patterns of behavior evolved by natural selection. A more recent dispute concerns the extent to which facial expressions are voluntary, performative strategies for social gain, as opposed to involuntary expressions of subjective feeling.

What Is at Stake in Discussions of Facial Expression?

Emotion can be expressed in the face, voice, posture, and gesture. Since Darwin, most researchers have concentrated on facial expressions. However, in recent years interest in vocal expression has increased, partly due to advances in acoustic technologies (Scherer, 2003). The nature and origins of facial expressions of emotion may not seem at first glance to be a matter of momentous concern for the social sciences and humanities. However, the emotions are widely believed to be a critical feature of moral agency, and are even more widely believed to be a critical part of aesthetic response. If all healthy people display, recognize, and respond to the same limited number of emotional expressions, this suggests a similar uniformity in emotion itself. Conversely, if human expressions of emotion are as diverse as human languages and if humans can only understand the expressive repertoire of their own cultural group, this might support a view of emotions themselves as culturally specific phenomena.

The issue of whether emotions fall into a limited number of discrete kinds has also been debated for its own sake, as a foundational issue in the psychology of emotion. Evidence about facial expression has played a critical role in these debates.

The Origins of Research on Facial Expression

The scientific study of facial expression began with the nineteenth-century anatomical investigations of Sir Charles Bell (1844) and G.B. Duchenne (1867/1990). The most influential work of the nineteenth century, however, was undoubtedly Charles Darwin's *The Expression of the Emotions in Man and Animals* (1872). The book started life as a chapter of Darwin's *Descent of Man* (1871), based on notes that Darwin had been accumulating since the 1830s. The chapter grew so large that it became a separate work. In *Descent of Man*, Darwin aimed to show evolutionary continuity between human ethical behavior and animal behavior and also, via his theory of sexual selection, between the human aesthetic sense and the aesthetic sense of animals. In *The Expression of the Emotions in Man and Animals*, he aimed to show evolutionary continuity between the human and animal emotions by demonstrating continuity between the facial expressions of humans and animals. Darwin explicitly targeted Bell's claim that the muscles of the human face were created by God to express human emotions. This led him to argue that many movements that now express emotion were vestiges of previous ways of life: "With mankind some expressions, such as the bristling of the hair under the influence of extreme terror, or the uncovering of the teeth under that of furious rage, can hardly be understood, except in the belief that man once existed in a much lower and animal-like condition" (Darwin, 1872: p. 12). Some authors have denied that Darwin ascribed any current adaptive functions to emotional expressions (e.g., Fridlund, 1994). However, to take just one example, Darwin argued that humans (unlike chimpanzees) open their mouths when terrified because (unlike chimpanzees) humans must breathe through their mouth when fleeing. Many of Darwin's specific claims about the facial movements associated with particular emotions are supported by contemporary research. He also pioneered the use of photographs to test the ability of observers to infer emotional state from facial expression (see **Figure 1**; **Figure 2**).

The Affect Program Theory of Facial Expression

Darwin's work on emotional expression was neglected for the first half of the twentieth century. Anthropologists such as Weston La Barre (1947) and Ray Birdwhistell (1963) argued that culturally specific emotional states were signaled in a culturally specific code of facial expressions and gestures acquired by the individual during their upbringing. This culturalist tradition was displaced in the late 1960s by a powerful revival in the Darwinian approach. Many of Darwin's specific findings about facial expression were confirmed and extended, most notably by the psychologist Paul Ekman and his collaborators (Ekman, 1972). One famous experiment used subjects from the Fore language group in New Guinea with a minimum of prior contact with Westerners and their cultural products. These subjects were given three photographs, each showing a face, and told a story which was designed to involve only one emotion. They were asked to pick the photograph showing the person in the story. This method has the advantage that no translation of the names of emotions is needed. The subjects were highly successful in picking the photograph intended to express the emotion appropriate for each story. The New Guinean subjects were also asked to act out the facial behavior

Figure 1 Photographs used by Darwin to test the recognition of emotion from facial expression. 1–3, Degrees of mild amusement; 4, impassivity; 5, true smile; 6, false smile. Note the electrodes used by Duchenne to stimulate the muscles.

Figure 2 Some photographs used in Ekman and his collaborators' research on facial expression. From top left: anger, fear, disgust, surprise, happiness, and sadness. Source: Ekman, P., Friesen, W.V., 1975. Unmasking the Face: A Guide to Recognizing Emotions from Facial Clues. Prentice-Hall, Englewood Cliff, New Jersey, © Paul Ekman. Reproduced with permission.

of the people described in the stories. Videotapes of their responses were shown to US college students. The students were generally accurate in their judgments of the emotion intended by the New Guineans. The six facial expressions that figured in these experiments were labeled surprise, joy, sadness, fear, anger, and disgust. These and a seventh initially not distinguished from disgust but later labeled contempt, became the basis of the revival of the Darwinian approach to expression.

Ekman conceptualized facial expressions as key components of 'affect programs,' complex patterns of facial and other actions controlled by the central nervous system and triggered in response to some specific stimulus (Ekman, 1984). This conceptualization derived, ultimately, from the idea of a 'fixed action pattern' as it figures in the classical ethology of Konrad Lorenz and Niko Tinbergen. These founders of the modern study of animal behavior rediscovered Darwin's work on the emotions and interpreted it as prefiguring many of their own ideas (Lorenz, 1965). Emotions, they argued, were innate patterns of behavior that had evolved by natural selection. Darwin's emphasis on the vestigial nature of many human facial expressions was interpreted using the ethological concept of ritualization (Tinbergen, 1952). Patterns of behavior that once served a practical function, such as opening the mouth and retching in disgust, were retained and modified by natural selection because of their value as signals. Hence, the primary biological function of facial expressions in humans is as a signal of the person's emotional state. The distinctive experimental paradigm of classical ethology was the 'deprivation experiment,' which aimed to show that an animal will produce a pattern of behavior even when it is deprived of the opportunity to learn that behavior. The human ethologist Irenaus Eibl-Eibesfeldt (1973) examined the facial movements of children born deaf and blind and showed that these children used the same patterns of facial action as other children to display their emotions. He concluded that these behaviors were evolved features of human nature.

Ekman and his collaborators explained cultural differences in the expression of emotion with the concept of a 'display rule.' This concept is exemplified by an experiment in which American and Japanese college students were shown neutral and stress-inducing films while alone in a room. The repertoire of facial behaviors shown during the stress phase by the two sets of subjects was very similar. However, when an experimenter was introduced into the room and allowed to ask questions about the subject's emotions as the stress film was shown again, the facial behavior of the Japanese diverged radically from that of the Americans. Video analysis showed the momentary occurrence of negative emotional expressions and their replacement with polite smiles. An important feature of the display rule conceptualization of cultural differences is that the evolved expressions remain intact but interact with

culturally specific behaviors to determine the observable pattern of facial action.

Ekman and collaborators' theory of discrete facial expressions of emotions retains a special status in the study of emotion and its expression because of the close relationship between the discrete emotions model and the widely used technology for coding facial expression (FACS – Facial Action Coding System) whose use was pioneered by Ekman and collaborators. FACS is a set of objective, anatomical measures that need not be used to classify emotions into a small number of discrete categories; but that use of the method is, for example, integrated into the training manuals for FACS coding.

Universality and Cultural Specificity

The research leading to the affect program theory and subsequent discussion have helped to clarify issues about the universality of emotion. The affect programs have the same output across cultures, but they do not have the same input. There are some universal elicitors of affect programs in childhood, such as very loud noises, which elicit fear. There are also systematic biases in the conditioning of affect program responses that could lead to a convergence in the eliciting conditions for adult responses. The general picture, however, is that affect programs come to be associated with whatever stimuli locally fulfill a broad functional role, so that the fear affect program comes to be associated with whatever locally constitutes a threat, the disgust response with whatever locally appears noxious or unclean, and so forth (for a good introduction to work in this area, see Ekman and Davidson, 1994: pp. 144–178). Distinguishing between the universality of outputs and that of inputs makes it clear that at least some disputes over the universality of emotion is merely semantic. Universalists regard two cultures as manifesting the same emotion when they respond in the same way to different stimuli. Their critics insist that having the same emotion means responding in the same way to the same things.

Further clarification results from distinguishing the question of whether emotions are pancultural (found in all cultures) from the question of whether emotions are universal (found in all healthy individuals). The types of evidence normally gathered by universalists are designed to show that emotions are pancultural and have little bearing on the question of universality. Emotions might be pancultural but still be like blood type or eye color, with several different types of individual in each population. Models of the evolution of social emotions sometimes predict that competing types will be maintained in the same population through competition. It is surprising that the issue of whether emotions have evolved is still so strongly linked to the issue of whether there is a single, universal, human emotional nature.

Finally, the debate over universality could be clarified by abandoning the last vestiges of the traditional dichotomy between learned and innate behaviors. Some critics have argued that a biological perspective on emotion is inappropriate merely because the emergence and maintenance of emotional responses depends upon environmental factors. Conversely, evidence that emotions are pancultural and thus likely to be the products of evolution is still thought to imply that these emotions are genetically determined and resistant to modification by environmental changes. These inferences ignore the fact that the environment plays a rich and constructive role in the development of even the most stereotypically biological traits, such as bodily morphology or sexual behavior. Evolved emotions, like the rest of evolved psychology, will likely make use of many reliable features of the environment of the developing child in order to construct and maintain themselves.

If facial expressions of emotions depend on both genetic and environmental factors in development, as it is commonly assumed all phenotypes do, then they will be open to cultural and individual variation as a result of environmental variation, as well as genetic variation. Some recent work in the psychology of facial expression explicitly adopts this perspective: Elfenbeim et al. (2007) suggest the evidence base favors both universality and cultural specificity, and that research should focus on the ways in which an underlying 'universal grammar' of emotional expression is affected by culturally specific emotional dialects. Parkinson (2012) suggests that research on emotional expression should articulate more precisely the ways in which environmental factors influence phylogenetic, ontogenetic, and moment-by-moment social transactions, rather than continuing to fixate on the question of the universality of expressions. Griffiths (1997) suggested that questions of universality can often be usefully reframed in terms of the biological concept of 'homology': Are two emotions in different individuals or cultures homologous, that is, are they modified forms of a response in a common ancestor of those individuals or cultures?

Contemporary Alternatives to the Affect Program Theory

Skepticism about the affect program view of emotion, as well as of emotional expression, has been articulated most clearly in recent years by James A. Russell (2003) and Lisa Feldman Barrett (2006a,b) under the label of 'psychological constructionism.' Russell and Barrett object to affect program theory for taking emotion words like 'anger' and 'fear' as psychological primitives. They claim that the fundamental building block of emotion is 'core affect'; a subjective awareness of one's bodily state along two dimensions, valence (pleasure to displeasure) and arousal (activation to deactivation). Core affect becomes emotion only when top-down processes of categorization couple one's affective bodily state to an external event. For example, when a bushwalker couples his sudden sweating and increased heart rate with the fact that he can see a snake nearby, he labels his experience as one of 'fear.' If he did not categorize his experience in this way, he would not be feeling the emotion of fear. Because this ability to categorize requires social learning, and because social learning varies by culture, core affect theory opposes universalism about discrete emotions and about their expressions. However, Russell and Barrett think that the underlying processes of valence and arousal are universal, even if their means of expression are necessarily mediated by culturally specific factors.

Barrett and Russell are part of a wider group of emotion researchers who have questioned the affect program theory's

account of the production and interpretation of facial expression (Russell and Fernandez-Dols, 1997). However, not all of these authors subscribe to Russell and Barrett's psychological constructionist account of emotion. Some, for example, are more concerned with the interpersonal nature of emotions, and with the idea that expressions are primarily signals, rather than expressions of an internal, motivational state (Fridlund, 1991; Parkinson et al., 2005). Some critics have offered methodological criticisms of the work of Ekman and his collaborators. They are critical of the use of forced choices from a list of emotion terms dictated by the experimenter. This procedure forces a range of responses to a range of facial signals into a few boxes defined by the experimenter. It cannot provide evidence for the existence of a limited number of discrete facial expressions, since this assumption is built into the experimental procedure. On the positive side, critics of the affect-program view have produced considerable evidence of 'audience effects' on the production of emotional expressions. This is interpreted as evidence that expressions are produced for the benefit of the audience rather than to express the feelings of the person making the display. This suggests that the affect program theory exaggerates the automated nature of emotional expressions and neglects their voluntary, performative aspect.

While they criticize the experiments usually taken to establish the universality of emotion, many critics accept that emotional expressions have evolved and would therefore presumably expect the flexible signaling system they describe to be at least substantially pancultural. Alan Fridlund (1994) argues that an evolutionary perspective actually favors the view that emotional expression is a form of paralanguage, since involuntary signals of true emotional state would be subverted by the evolution of dissimulation and deceit. While this is an important perspective on the evolution of emotional expressions, it does not constitute the decisive argument that Fridlund seems to suppose. Veridical signals do evolve in nature, often by making use of the so-called hard-to-fake signals. The cost of being unable to suppress a signal of emotional state may be balanced by the advantage of being believed. A purely theoretical argument based on the evolutionary dynamics of signaling systems seems more likely to support the view that "examples of emotional behavior lie along a continuum from expression to negotiation" (Hinde, 1985: p. 989) than a purely expressive or purely manipulative picture of emotional expression.

Conclusion

Facial expressions of emotion are an important site for the debate between universalism and cultural specificity about emotion because both sides believe that here they can offer substantial evidence for their positions. An examination of this evidence need not serve only to support one or other side of the debate. The actual details of emotional expression, its evolution, and its development in the individual can be used to question the validity of the dichotomies between biology and culture, fixity and malleability, universality and idiosyncraticity which are assumed by both sides.

Abstract

This article addresses emotion and cognition by first introducing basic models where emotions are thought to be discrete entities (e.g., anger, sadness, happiness). Appraisal theories of emotion are introduced next, including psychological construction approaches, where emotions are classified as emerging from specific ingredients of the mind, and moves away from the basic emotions approach and emphasizes the variability and variety of emotion categories across cultures. Recent and past empirical evidence is provided throughout the article, providing support for both basic and nonbasic theories of emotion. Finally, clinical implications on emotion and cognition are discussed along with providing a life-span perspective.

Introduction

Traditionally, an encyclopedia entry on 'the role of emotion in cognition' might consider different emotions, such as anger and fear, and present theory and some data considering how each of these different emotional states might influence (and perhaps 'direct') cognitive operations like attention, memory, and decision-making. In this updated article, we will consider this approach as well, but hope to embed that approach within larger conceptual frameworks that provide complementary and alternative ways of considering how emotion and cognition may relate to each other. In the first part of the article, we consider how different definitions of emotion lead to different views of the role of emotion in cognition (and the place of cognition in emotion). In the second part, we present some relevant empirical findings. In the third part, we discuss how a clinical and life-span perspective may also inform the study of emotion–cognition links.

Approaches to Emotion and Their Implications for Emotion–Cognition Links

Basic Emotion Models

Asking simple questions about how emotion influences cognition may be most associated with a view of emotions known as the 'basic emotions' view. In a basic emotion model, each discrete emotion triggers a set of evolutionarily derived biological responses. A discrete emotion when triggered by stimuli in the environment initiates a cascade of behavioral, expressive, autonomic, and neuroendocrine responses that are specific to that emotion. The classic example is as follows: You are approached by a bear (stimulus). The bear triggers an emotion (likely fear). The fear response goes off like a bomb and sets in motion a set of programmed responses (e.g., widened eyes, increased heartbeat, sweaty palms) that are biologically programmed to help you survive the bear chase.

An important feature of basic emotion models is that each emotion (e.g., 'fear,' 'anger,' 'sadness') is a unique mechanism that causes a unique mental state with unique, measurable outcomes. Further, the mental states and measurable outcomes (associated with each emotion) occur *consistently* across every instance of that emotion and *specifically* only in that emotion (Ekman, 1972; Panksepp, 1998; Izard, 1993; for recent reviews, see Ekman and Cordaro, 2011; Gendron and Barrett, 2009; Gross and Barrett, 2011).

From a basic emotion perspective, the answer to the question 'What are the cognitive prerequisites for emotion?' would likely be 'minimal.' Basic emotion theorists postulate that low-level sensory information is processed for emotional relevance, quickly and automatically, activating a dedicated neural pathway that, in turn, triggers a cascade of responses to organize behavior and physiology. Further, theorists propose that this processing occurs very rapidly and does not require any conscious awareness or higher-order cognitive processing (Adolphs, 1999; Ekman and Davidson, 1994; LeDoux, 2000; Levenson, 2011; Panksepp, 1998; Tracy and Randles, 2011). To the extent that discrete emotions reflect different antecedent events and orchestrate distinct behavioral responses, it is logical that certain emotions would have certain effects on attention and memory aligned with the behaviors associated with that particular emotional response.

Appraisal Models

Appraisal theories view emotional experiences as a process of changes between components. These components can include environment evaluation, motivation, peripheral physiological response, expressive and instrumental behavior, and subjective feelings. In nearly all appraisal views of emotion, cognition is a necessary prerequisite for emotional experience. Cognitive processes or 'appraisals' are considered antecedent events that must occur in order for a response to take place. Some appraisal models (particularly early models, e.g., Arnold, 1960; Lazarus, 1998) refer to appraisals as specific cognitive antecedents of emotion that make meaning from the world. In these models, appraisals can be thought of as a set of switches, that, when configured in certain patterns, trigger biologically basic emotional responses characterized by behavioral or physiological outputs or by a strong, almost inescapable tendency to interact with the world in a particular way, an 'action tendency' (for recent reviews, see Moors, 2013). Other appraisal models

do not view appraisals as causes of an emotion. Rather, they are loosely coordinated action tendencies that are configured based on context and may or may not come to fruition.

Whereas some appraisal theories offer a more general mechanism of appraisal in which attention is generally captured by stimuli that are intrinsically relevant to the individual and an emotional response follows that relevance appraisal, there are also versions that provide a more detailed account of what particular appraisals may be critical. For example, the component process model posits specific evaluations that result in particular emotional responses such as novelty, intrinsic pleasantness, and goal relevance. These evaluations include determining the implications and possible consequences of the stimulus or event, potential to cope with the consequences, and whether or not the event is aligned with self and/or cultural standards, in that sequential order (Scherer, 1984, 2001, 2013). All stimulus evaluation checks in this model depend on the valence determination from the previous check; thus, this entire process can be thought of as a filter system to determine how much a particular stimulus or event will be appraised by an individual and what emotion will result.

Most appraisal theorists agree that appraisals are automatic and often unconscious and that the appraisal process begins immediately following the onset of an emotion-eliciting stimulus. A few appraisal models, however, view emotions as a way of experiencing the world. In these models, cognition and emotion emerge and interact to form the content of that meaning (e.g., Clore and Ortony, 2008; Schwarz, 2010). Often called 'affect as information' or 'feelings as information,' these theories propose that we use our current affective state as information about the way the world is. From this perspective, emotions and cognition are bidirectional and influence each other.

In one classic experiment, participants were asked about their life satisfaction on sunny and rainy days. Participants who were not asked about the weather reported significantly less life satisfaction on rainy days than on sunny days. For participants who were reminded about the weather, sun or rain made no difference in their ratings of life satisfaction (Schwarz and Clore, 1983). These studies (and others) suggest that people can use their momentary affective states as information about themselves and the world around them.

Psychological Construction Model

Psychological construction models view emotions as emerging from more basic elements and/or systems of the mind, rather than emotions being the basic building blocks of the mind. Instead of breaking down emotions into specific emotion categories (anger, fear, happiness, etc.), psychological construction theories emphasize the variability in the number and variety of emotion categories both across individuals and across cultures. In psychological construction models, cognition and emotion are not separate processes that occur sequentially. Rather, basic psychological ingredients (such as language, affect, and executive attention) combine to form discrete emotion experiences. Psychological construction theories do not subscribe to a basic emotions account that all humans express specific emotions that fall into specific emotion categories. Instead, psychological construction approaches view emotions as being emergent, where emotion instances are created when afferent information from the body is made meaningful in relation to external surroundings. In order to be made meaningful, 'core systems' or 'ingredients' of mental states are utilized where a human has a system(s) in place for representing sensations related to the body (e.g., pounding of the heart) and a separate system for making sense of these sensations in relation to the situation (e.g., giving a speech in front of a large crowd) (Barrett, 2013, 2009a). One psychological construction model, the conceptual act model, proposes that humans are constantly picking up cues from the body and the external world and simultaneously categorizing them according to their preexisting conceptual knowledge and past experiences (Barrett, 2006, 2009b; Lindquist, 2013).

In terms of emotions having specific neural components, the iterative reprocessing model (an additional psychological construction theory) emphasizes that many different patterns of neural activity can create a single mental state or emotional episode. Some theories (specifically the conceptual act theory) claim that emotions have no localization to any one particular brain network, while iterative reprocessing model believes in a 'processing framework' in which sensory information flows through a hierarchical organization of the brain but is continually reinterpreted and shaped according to an individual's goals, values, desires, and intentions (Cunningham et al., 2013; Cunningham and Zelazo, 2007).

In summary, psychological construction approach theories emphasize that emotions cannot be reduced to specific components (such as facial expression, valence, arousal, neural localization, physiological response) and instead emotions are continuously redefined and categorized at an individual level depending on the situational context and the state of the body (Wilson-Mendenhall et al., 2011). In terms of cognition, psychological construction models assert that specific mechanisms are necessary to construct an emotional episode, such as memory and categorization (learning), and can be guided by attention or perception of visual images and auditory sounds.

From Conceptual Models to Research Findings

Clearly, there are different ways of conceptualizing the role of discrete emotions in attention and cognition, and these vary in somewhat fundamental ways as a function of how emotions themselves are defined. Nonetheless, they each provide a way to investigate how different types of emotional states may influence various kinds of cognitive processing. Below, we review some recent research in this area.

Some theorize that discrete emotions, or emotions that are short-lived, intense, and arise from stimulus-specific events, have clear effects on attention and cognition (Ekman and Cordaro, 2011; Izard, 2011; Levenson, 2011; Panksepp and Watt, 2011). These findings tend to be most consistent with the basic emotions approach. Emotions of negative valence (e.g., disgust, fear, sadness, anger, etc.) differ to the extent that they influence cognition, particularly on appraisals that involve judgment and decision-making. For instance, disgust, an emotion often recognized from a feeling in the 'gut' (often inducing feelings of nausea or other gastroenteric nervous system responses) and from its distinct facial expression

(Ekman, 1972; Tybur et al., 2013), has been found to influence cognition in terms of shaping moral judgments. In empirical designs, subjects induced to experience feelings of disgust (e.g., via smell, taste, etc.) tend to judge acts or situations (e.g., first-cousin marriage) as being more wrong or less acceptable compared to subjects not experiencing disgust (Schnall et al., 2008; Eskine et al., 2011). Thus, researchers theorize that disgust intuitions serve as an 'input to systems' that serve to aid in decision-making about what is morally appropriate versus what is not (Pizarro et al., 2011; Tybur et al., 2013).

Fear has been thought to have deep evolutionary origins stemming from the need to survive and to be constantly aware of potentially threatening surroundings. Due to this, the experience of fear places a strong control on attention, demonstrated in a study conducted by Öhman et al. (2001) in which participants were instructed to detect a target stimulus in the face of distractor stimuli. Participants more quickly identified the target stimulus if it was fear-relevant target (e.g., pictures of snakes and spiders) compared to nonfearful target (e.g., mushrooms, flowers), providing evidence that fearful target objects direct visual attention. Furthermore, the emotional experience of fear leads to the need for protection and escape and often leads to higher estimations of the likelihood of risky events occurring (Angie et al., 2011).

Sadness, often evoked by a substantial loss to an individual (e.g., the death of a loved one), turns attention inward and promotes detail-oriented information processing. The emotional experience of sadness allows for a 'pause' and a cognition update to revise goals and plans through the decrease of physiological arousal, which facilitates problem-solving (Welling, 2003; Bonanno and Keltner, 1997; Oatley and Johnson-Laird, 1996). Anger, an emotion often arising from events or people threatening an individual's outcome in a particular situation, has been found to be associated with a sense of individual control and evokes risk-seeking choices and subsequent behaviors. The experience of anger often triggers physiological responses resulting in increased blood flow to facial regions, thus linking perception of the color red to anger. In fact, research has found that activating anger concepts in participants (e.g., by categorizing anger-related words such as 'furious' or 'irate') led to the interpretation of perceiving ambiguous color objects as being red (Fetterman et al., 2011). In addition to the experience of anger resulting in 'seeing red,' anger can also lead to biased information processing, which can have detrimental effects on individuals. For example, anger initiates cognitive errors, such as misattributing causation, or "making negative assumptions while ignoring the possibility of other interpretations" (Martin and Dahlen, 2007: pp. 156) and overgeneralization, or usage of broad concepts and language such as 'everyone,' 'never,' or 'always' (Martin and Dahlen, 2007).

Generally, emotions of a positive valence have been theorized to initiate exploration or the broadening of attention, expanding cognition and creativity (Fredrickson, 1998, 2001; Gasper and Clore, 2002; Isen, 1987; Rowe et al., 2007). In an eye-tracking study conducted by Wadlinger and Isaacowitz (2006), participants induced into a positive mood state fixated more on peripheral stimuli (e.g., images of a similar valence) than central stimuli compared to control participants, providing evidence that positive emotional states promote attentional breadth via visual attention. For example, the experience of happiness has been found to promote creativity in studies assessing problem-solving task accuracy, suggesting that the experience of positive affect "increases the tendency to combine material in new ways and to see relatedness between divergent stimuli" (Isen et al., 1987: p. 1130). Joy, often termed as happiness (Lazarus, 1991), initiates the thought–action experience by increasing the urge to 'play,' involving increased exploration, invention, imagination, and can have long-standing positive effects on building an individual's physical, intellectual, and social skills (Fredrickson, 1998). Gratitude, or the experience of feeling grateful or thankful, is a positive emotion that has recently received more attention in emotion research, particularly in the domain of social functioning (Algoe, 2012; Algoe et al., 2013). Cognitive-emotion theories emphasize that the feeling of gratitude is associated with the recognition and appreciation of an altruistic gift or action and results in increased cognitive capacity to empathize with others (Lazarus and Lazarus, 1994; McCullough et al., 2001). Contentment, a low-arousal positive emotion also termed as 'tranquility' or 'serenity,' arises from appraisals of situation safety, certainty, and requiring minimal effort (Ellsworth and Smith, 1988). The experience of contentment prompts individuals to cognitively integrate recent life events and circumstances into their overall self and worldview, resulting feelings of connection or 'oneness' with the world around them (De Rivera et al., 1989; Fredrickson, 1998; Izard, 1977).

In addition to negative (e.g., anger, fear, etc.) and positive (e.g., happiness, joy, etc.) emotions, the experience of awe (otherwise termed as 'astonishment,' 'interest,' 'amazement,' 'surprise') can be evoked by the occurrence of rare events perceived by the viewer as 'fascinating,' including viewing something unknown for the first time, or experiencing what one would consider to be a 'miracle,' and can be both positive and negative in nature (Ekman, 1992; Frijda, 1986; Keltner and Haidt, 2003). The emotional experience of awe encompasses feelings of both perceived vastness (e.g., larger than the self) and the need for accommodation (e.g., the adjusting of mental structures to assimilate an entirely new experience) (Piaget and Inhelder, 1966/1969). The process of accommodation can leave one feeling confused, small, and powerless if the conception of the vast experience is not made sense of, or enlightened if the individual succeeds during the accommodation process and makes sense of the vastness (Keltner and Haidt, 2003).

Other research has suggested that whether or not cognition is impaired or enhanced by emotional information depends on the nature of the emotional stimuli. In one such study, Pessoa et al. (2012) found that participants exhibited strong response inhibition when presented with fearful and happy facial expressions relative to neutral faces, suggesting that in one case emotional stimuli (regardless of valence) serve to facilitate cognition (via increased ability to not respond to a stimulus in a stop-signal task). However, follow-up studies manipulating the nature of the fearful facial expression by a conditioned shock to the response stimulus showed decreased response inhibition in that participants struggled to stop responding. This finding suggests that arousal, but not valence, may play

a primary role in emotion–cognition interactions and provides evidence that the type of emotional stimuli and the effect that it has on the individual (and perhaps the appraisal) will either facilitate or inhibit cognition.

Furthermore, emotionally salient events/stimuli are thought to "burn longer and brighter in the mind's eye" (Todd and Anderson, 2014: p. 12) by capturing visual attention and enhancing visual cortex activation. Due to this, emotionally evocative information has been thought to have privileged perceptual processing by grabbing attention even during states of diminished attentional resources (e.g., situations of limited memory consolidation capacity). However, there is a plethora of visual stimuli in the environment both emotionally salient and neutral, so the question becomes at what point does the visual information reach consciousness, and just how and why does some information reach conscious awareness, while other information passes through, unfiltered? Some research has suggested effects of particular emotional expressions on attention, in ways that would then have implications for cognitive processing (Ekman et al., 1969; Tracy and Matsumoto, 2008; Susskind et al., 2008). For example, when one encounters a spider, a fearful facial expression is often produced that includes elongation of the muscles surrounding the eyes, nose, and mouth. Thus, the sensory organs are essentially 'open' and the individual will experience increased sensory vigilance to the environment. During the emotional experience of disgust, the facial expression produced has been prototyped by researchers to have the exact opposite muscle activity as fear, resulting in clenched muscles surrounding the eyes, nose, and mouth (Susskind et al., 2008). During the facial expression of disgust, individual experiences sensory rejection of the surrounding environment, resulting in diminished attention to the environment. It has been proposed that facial expressions might, in fact, serve the physical purpose to modify perception by visually restricting access to sensory information during contamination (disgust) or increasing access to sensory information during threat (fear) (Todd and Anderson, 2014; Tybur et al., 2013).

Beyond effects of particular emotional states on attention and cognition, positive and negative states more generally may have effects as well. Appraisals resulting in sustained emotional states (e.g., positive or negative emotional states) have been found to alter neurotransmitters function and thus influence subsequent cortical processes responsible for motivation, attention, etc. For example, negative emotional states have been hypothesized to narrow perceptual processing causing decreased detection and peripheral exploration, whereas positive emotional states have been hypothesized to broaden attention to the periphery or to task-irrelevant stimuli in an unbiased, flexible, exploratory manner (Todd and Anderson, 2014).

Other evidence further suggests that the affective state of an individual can actually predict visual attention toward stimuli in the environment. One such study induced positive or negative affective states in participants followed by quickly flashing images of facial expressions containing different affective states (scowling, smiling, or neutral) or images of neutral houses to each eye. Affective expression states dominated visual awareness (measured by keystroke response times) compared to the images of houses to participants in negative affective states, while images of smiling faces dominated visual awareness compared to neutral expression or scowling to participants in positive affective states (Anderson et al., 2011).

Research conducted on positive affective states in particular has shown that positive affect leads to the broadening of visual attention through the relaxation of attentional selectivity. Rowe et al. (2007) had participants induced into happy, sad, and neutral affective states complete a flanker task in which they were prompted to identify a central letter that was surrounded by congruent or incongruent similar-looking letters (e.g., 'H and N') and complete a word solving/generation task. Happy participants were able to generate more words in the word problem-solving task compared to those in sad or neutral states, underlining previous work suggesting that positive affective states lead to an increased capacity for creativity (Isen et al., 1987). Additionally, participants in happy moods also demonstrated greater flanker interference, meaning that participants in positive states were slower to respond to the central letter in the task because they were likely attending to the surrounding letters. This decreased response time does provide further evidence for attentional broadening in positive states; however, the researchers do point out that positive moods may only facilitate tasks that require a more global processing style (e.g., problem-solving tasks) but may actually impair tasks requiring selective visual attention. In summary, this work provides evidence for top-down influences of affective states on attention and furthermore suggests that affective states may serve to bias visual attention by shifting the breadth of attention in the environment, particularly while in positive affective states.

Clinical Implications

Affective disorders such as depression and anxiety may also influence attention and cognition, thus providing an additional window onto how emotion and cognition may be related. In research studies, clinically anxious individuals have been found to possess a more extreme attention bias compared to non-anxious individuals in a dot-probe task in that the clinically anxious individuals respond more to mildly threatening emotion words compared to nonanxious individuals. Since fear is theorized to have an evolutionary component, it is reasonable to assume that all individuals will respond to more extreme threat stimuli such as a large spider or a skidding automobile. However, fear turns to anxiety when this 'danger threshold' is exceeded and an individual begins responding with equal fear intensity to nonthreatening stimuli (MacLeod et al., 1986). Additionally, people who have experienced trauma and suffer from posttraumatic stress disorder (PTSD) demonstrate attentional biases toward trauma-related stimuli, including trauma words in a Stroop task (Beck et al., 2001; Buckley et al., 2000; Vythilingam et al., 2007). For example, Beck et al. (2001) administered a Stroop task containing accident words, pain words, positive words, and neutral words to participants who have experienced motor vehicle accidents. Participants who had PTSD symptoms as a result of the accident showed decreased response times to accident and pain-related words in the Stroop task, providing evidence for an attentional bias toward trauma-related stimuli. Furthermore, sadness turns to depression when the 'pause' or cognitive reset that occurs during a typical emotional

experience of sadness becomes prolonged. In these cases, individuals engage in what is termed rumination, or preservative thinking about upsetting symptoms and the causes and consequences of the symptoms without initiating problem-solving strategies that may resolve the distress (McLaughlin and Nolen-Hoeksema, 2011). Clinically depressed individuals have also been shown to possess an attentional bias toward negative information in that they have a difficult time disengaging from negative material once it captures their attention (Gotlib and Joorman, 2010).

Emotion in Cognition across the Life span

Another approach to considering the dynamic and bidirectional interrelationships between emotion and cognition is to investigate changes in the both across development. This has been an area of particular interest since Laura Carstensen proposed a motivational theory, socioemotional selectivity theory, which suggests fundamental shifts in how emotions and cognitions may be linked across adulthood (Carstensen et al., 1999; Carstensen, 2006). According to the theory, limited-time perspective leads individuals to prioritize emotional over other types of goals; in other words, limited time makes people care about feeling good. As older adults have a more limited-time perspective, they are thought to prioritize emotional goals, and this goal shift is hypothesized to lead older adults to display 'age-related positivity effects' in their cognition, focusing attention and memory on positive rather than negative stimuli (see also Reed and Carstensen, 2012). This is then an effect of an emotional goal on cognition and leads to the suggestion that older adults' cognition is directed by their desire to achieve positive emotional states. Interestingly, there is also some evidence that engaging in emotion regulation leads to more downstream cognitive costs for younger rather than older adults (Scheibe and Blanchard-Fields, 2009). While these findings about age differences in emotion–cognition links do not speak directly to the general issues raised above, they suggest that developmental considerations may broaden the scope of research on how emotion and cognition may reciprocally interact in a way that may also feed back to the more general theoretical models that guide researchers in the field.

Conclusions

Clearly, individuals' emotional states are related to how they attend to information in their environment and also influence cognitive processing of information from the environment. There is evidence that specific emotional states impact attention and cognition, and also that more general affective states such as positive and negative affects do as well. To some degree, the type of research that has been done and the questions that have been asked in particular studies vary as a function of the conceptual model of the nature of emotion held (either implicitly or explicitly) by the study authors. Researchers who subscribe to a basic emotions or appraisal approach tend to ask about the cognitive effects of specific emotional states (such as fear, anger, disgust), whereas psychological construction approaches that view core affect as a key psychological primitive would instead focus on how valence and arousal influence attention and cognition. Future work will need to determine how research findings can either be used to test conceptual models against each other or can be integrated across models to provide a more comprehensive account of how emotion, broadly construed, can influence cognition, also broadly construed. That these processes also seem to vary by clinical diagnosis, as well as by age, further suggests the need for a nuanced conceptual model, as well as empirical investigations that consider individual differences as well as the effects of specific emotional or affective states.

Abstract

Here we outline the development of the evolutionary study of emotion. We begin with the work of Charles Darwin, who initiated the study of the evolution of emotion. Since then, at least three different approaches to the subject have emerged in the literature. The orthodox 'basic emotions' or 'affect program' view developed in the 1960s out of human ethology and psychological and physiological studies of emotion. Both the Evolutionary Psychology movement and the transactional approach to emotion developed in the 1960s and 1970s, amending the orthodox approach in different ways. In recent years, particular attention has been paid to the evolution of moral emotions, such as shame, pride, and moral disgust.

The Darwinian Legacy

Darwin did not see his *Expression of the Emotions in Man and Animals* (1872) as a theory of the evolution of emotion itself, because he defined emotions as subjective feelings. Following Herbert Spencer, Darwin distinguished emotions as feelings caused by external states, in contrast to feelings caused by bodily states, such as hunger and pain. Later evolutionary theorists have preferred behavioral and physiological definitions of emotion, with the result that Darwin's theory of the expression of emotions has been interpreted as a theory of the emotions themselves.

Darwin proposed three principles of the evolution of expression. The most important of these was the 'principle of serviceable associated habits,' which is a straightforward application of Darwin's theory of instincts to the case of emotion. Darwin believed that instinctive behaviors derive from habits. The consistent acquisition of the same habit for many generations causes it to become hereditary, or instinctive, as a result of the inheritance of acquired characteristics, of which Darwin was a firm believer. Most of the distinctive behaviors associated with particular emotions, such as the erection of the hair in fear, reflect long since vanished lifestyles in which those behaviors were rewarded and reinforced in each generation until they were finally incorporated into the hereditary material as instincts. Darwin supplements this principle with two others, the 'principle of antithesis' and the 'principle of direct action.' The antithesis principle postulates an intrinsic tendency for opposite states of feeling to produce opposite behaviors. Darwin remarks of a submissive dog that,

> Not one of the movements, so clearly expressive of affection, are of the least direct service to the animal. They are explicable, as far as I can see, solely from their being in complete opposition or antithesis to the attitude expressive of anger. (Darwin, 1872: p. 51)

Darwin explains the behaviors left over after the application of these two principles as the results of the 'direct action' of the nervous system. Excess nerve energy built up in an emotional episode is released in behaviors such as sweating and trembling for no other reason than that it must go somewhere and that these channels are physiologically available for its release.

The Ethological Tradition

The founders of ethology saw themselves as the direct heirs of Darwin's work on mental evolution (Lorenz, 1965). They retained Darwin's principles, but reinterpreted them to fit the theory of evolution as it emerged in the 1930s in the 'modern synthesis' of Darwinism and Mendelian genetics. The principle of serviceable associated habits was transformed into the ethological concepts of 'ritualization' and 'derived activity' (Tinbergen, 1952). Derived activities are behaviors that originally evolved for one purpose but were later selected for another purpose. Ritualized behaviors are derived activities that originally evolved to fulfill some practical function but which were later selected to function as signals. Thus, although piloerection in fear and rage does little to make a human being appear larger to an opponent, it does communicate their emotional state. Derived activities require a distinctive, two-stage form of evolutionary explanation. They cannot be understood purely in terms of the function they currently perform and the selection pressures that currently maintain them in the population. This is particularly obvious in the case of signals. Piloerection is not intrinsically better as a signal of fear than smiling or laughing. This particular behavior was selected as a signal only because it was already associated with fear in the distant past. It was not associated with fear because it was a signal of fear, but because it made the animal appear larger.

The concept of ritualization allowed ethology to reconstruct Darwin's principle of serviceable associated habits while avoiding his commitment to the inheritance of acquired characteristics. Darwin's descriptions of the psychological rewards that led to the reinforcement of emotional behaviors are equally plausible as descriptions of the original selective advantage of those behaviors. Darwin's other two principles were similarly open to reinterpretation. The principle of antithesis was explained by the selective value of unambiguous signals: it may be important for an animal to signal clearly that it is not aggressive. Hence there can be selection of behaviors

merely because they look different from the behaviors that signal aggression. The principle of direct action was transformed into the ethological concept of displacement activity. Early ethologists shared Darwin's view that instinctive motivations cause a build up of mental energy that must be released in some behavior or other. Displacement activities "serve a function as outlets, through a safety valve, of dangerous surplus impulses" (Tinbergen, 1952: p. 23). An example commonly given is that of an angry cat that is unwilling to attack and begins to wash itself. This wholesale reinterpretation of Darwin's three principles worked so smoothly and allowed the retention of so much of the detail of Darwin's work that the early ethologists seemed almost unaware of the differences between Darwin's theory and their own (Lorenz, 1965).

The Affect Program Theory of Basic Emotions

Darwin's detailed accounts of human facial expressions were confirmed and extended during the 1960s and early 1970s and many of his suggested homologies between human and primate facial expressions were confirmed. It became generally accepted that some emotional expressions, the so-called basic emotions, are found in all cultures and have an evolutionary history at least as long as the history of the human species (Ekman, 1973). The basic emotions are usually referred to as fear, anger, disgust, contempt, joy, sadness, and surprise, although in normal usage each of these words has a much wider meaning. During the same period, the hydraulic metaphors that the ethologists had used to describe psychological processes were replaced with a computational model of emotion. Each basic emotion corresponds to an 'affect program' stored somewhere in the brain. When activated, this program coordinates a complex of actions that include facial expression, autonomic nervous system changes, expressive vocal changes, and muscular–skeletal responses such as flinching or orienting. The concept of an affect program inherits many of the features of the ethological concept of a 'fixed action pattern.' Both concepts suggest that certain apparently complex behaviors are, in reality, atomic units of behavior that unfold in the same, stereotyped sequence whenever they are triggered. The affect programs are controlled by an 'automatic appraisal mechanism.' This is a specialized neural system that applies its own distinctive rules for stimulus evaluation to a limited set of data derived from the earliest stages of the processing of perceptual information. Considered together, the appraisal mechanisms and affect programs form a cognitive 'module' in the sense favored by more recent evolutionary psychologists (Barkow et al., 1992).

The affect program theory retains two distinctive features of the earlier, ethological model of emotions. First, emotional behaviors are an inevitable and involuntary accompaniment to the underlying emotional state and as such are reliable signals of that state. Second, deliberate attempts to disguise emotions are subject to 'leakage' from the operation of the involuntary emotional response. Voluntary attempts to suppress emotional behavior can only operate by simultaneously using the muscles involved in the expression for some other purpose. They cannot interfere with the actual operation of the emotion module.

The affect program theory was accompanied by an account of the evolution of the emotion system as an ancient form of cognition that had originally operated on its own and later been supplemented by higher cognitive functions. This view was supported by MacLean's theory of the 'triune brain,' according to which the emotions are located in the 'paleomammalian' portions of the brain, while higher cognitive functions are realized in newer, 'neomammalian' structures (MacLean, 1952). The survival of these ancient forms of behavior control in primates was explained by their value as fail-safe responses ensuring that vital behaviors are performed whenever necessary even if that means they are performed too often. Although MacLean's 'triune brain' is no longer accepted in its original form, this view of the emotion system as a collection of primitive but reliable fail-safe mechanisms remains influential (Panksepp, 1998).

Sociobiology and the Emotions

Sociobiology brought a new perspective to bear on the evolution of emotion in the 1970s and 1980s. It also moved the focus of investigation from the basic emotions to the moral and quasimoral emotions involved in human social interaction. Emotions such as trust, loyalty, guilt, and shame play an obvious role in mediating the competitive social interactions that were the focus of most research in human sociobiology. Numerous sociobiologists made brief comments to the effect that moral emotions must have evolved as psychological mechanisms to implement evolutionarily stable strategies of social interaction (Weinrich, 1980). Robert A. Frank (1988) suggested that the moral emotions evolved as solutions to 'commitment problems.' A commitment problem arises when the winning strategy in an evolutionary interaction involves making a binding but conditional commitment to do something that would be against one's own interests if the condition were ever met. If such a commitment is to be credible, some special mechanism is needed that would cause the organism to act against its own interests. Frank suggests that emotions such as rage and vengefulness evolved to allow organisms to engage in credible deterrence, threatening self-destructive aggression to deter a more powerful aggressor. Conversely, emotions such as love and guilt evolved to allow organisms to engage in reciprocal altruism in situations where no retaliation is possible if one partner fails to reciprocate.

Sociobiologists criticized ethology because it lacked a theoretical framework with which to predict how humans would behave, accusing it of being little more than descriptive natural history (Barash, 1979; Barkow, 1979). In contrast, sociobiology seemed to make strong predictions that clashed with some aspects of the affect program theory of basic emotions. From a sociobiological perspective it makes no sense for organisms to possess involuntary expressive behavior that freely communicates information about the animal's motivational state to anyone who has a use for it. The application of evolutionary game theory to emotional behavior predicts that this behavior will be designed to manipulate the expectations of other organisms rather than to transparently 'express' emotional states. This theoretical argument has been used by some to reject the affect program view of basic emotions.

Alan Fridlund (1994) has argued that emotional behavior should be regarded as a paralanguage of social signals whose production depends at least as much on an organism's social context as on its emotional state. Fridlund and other paralanguage theorists have documented 'audience effects' on the production of the basic emotions and have argued that this is inconsistent with the affect program theory. They have also tried to show that the classical facial expressions of emotion are not strongly correlated with the underlying emotional state and that people rely more on context than on behavior in attributing emotions to others (Russell and Fernández-Dols, 1997). It is unclear, however, that this data contradicts the predictions of the affect program theory. Signaling behavior exhibits audience effects in many organisms, such as domestic chickens, in which that behavior is presumably part of a highly stereotyped behavior sequence controlled by a relatively simple cognitive mechanism.

Mark Hauser has suggested that Fridlund's arguments bear on questions about the biological function of emotional behavior while the affect program model is concerned with the mechanisms that produce this behavior (Hauser, 1996: pp. 495–496). In some places, however, Fridlund does seem to be discussing the nature of the underlying emotional processes and not merely their biological function. Fridlund argues that since emotions are signals produced because of the impact they will have on other organisms, a particular emotion defined behaviorally need not correspond to any particular motivational state (emotion) of the organism producing it.

Evolutionary Psychology and the Emotions

The Evolutionary Psychology movement of the late 1980s and 1990s has been less inclined than sociobiology to question the accepted view of basic emotions. The evolutionary psychologists believe that the mind as a whole is made up of modules that operate independently of one another. Like the emotion system, these modules operate on specific kinds of data using algorithms that differ from those used by other modules. Hence, evolutionary psychology endorses the affect program theory of basic emotions, but wants to go further, both by adding to the complexity of the known affect programs and by finding modular mechanisms underlying other emotional behaviors. John Tooby and Leda Cosmides (1990) suggest a number of cognitive and behavioral systems that they would expect to receive output from the affect programs, in addition to those currently known to receive such output. They also suggest that the affect programs will be elicited by simple, perceptual stimuli that have played a recurrent role in human evolutionary history. Current empirical research suggests, however, that few simple perceptual stimuli elicit affect programs in the absence of any individual experience of those stimuli. Most evolutionary influences on sensitivity to simple perceptual stimuli seem to take the form of learning preparedness – the relative ease with which one association is acquired rather than another. Genuine pancultural antecedents of emotion seem to be relatively abstract states of affairs having to do with the significance of a situation for the organism and requiring local knowledge to translate them into perceptible features of the stimulus situation (Ekman and Davidson, 1994: Section 4, pp. 144–177).

The leading evolutionary psychologist David Buss has argued for the existence of a module for sexual jealousy, one of the additional modules predicted by Tooby and Cosmides. Buss argues that sexual jealousy has simple perceptual elicitors such as unusual scents, changed sexual behavior, excessive eye contact, and violation of rules governing personal space. Buss claims that "these signals alert us to the possibility of infidelity, since they have been statistically linked with relationship loss over the long course of human evolutionary history" (2000: p. 45). The jealousy module uses special-purpose algorithms and, like the basic emotions, it functions as a fail-safe mechanism: "Failing to detect an infidelity was more costly than mistakenly accusing an innocent partner of betrayal. Evolution, as a consequence, forged a hypersensitive defense system, designed to sound the alarm not just when an infidelity has been discovered, but also when the circumstances make it slightly more likely" (Buss, 2000: p. 224). When triggered, the module produces various forms of violence against female sexual partners, including, under certain environmental conditions, murder. A noticeable contrast between these recent theories and more traditional accounts of the evolution of emotion is the absence of the idea that emotions represent a more primitive form of behavioral control that can be contrasted to rational, planned action. The emotions are seen as just another cognitive module reflecting details of the environment of evolutionary adaptedness.

Evolution of the Moral Emotions

The important domain of human behavior that we call 'morality' is closely related to a number of emotions, sometimes collectively referred to as the moral emotions. These include guilt, shame, pride, embarrassment, indignation, and moral disgust. The role of these emotions in morality is part of 'moral psychology,' a field that bridges philosophy and psychology. Many of the research traditions discussed above have had views on the evolution of the moral emotions, but recent years have seen an increase in interest, particularly in moral disgust, shame, and pride.

Daniel Kelly (2011) presents a synthesis of much recent research on disgust. He argues that this emotion combines a taste-aversion mechanism with a mechanism for avoiding infection and parasitism. Kelly argues that disgust is uniquely human. It is an example of the co-option and developmental entanglement that occurs as an evolving lineage confronts new adaptive challenges and must solve them by modifying existing features. Both elements of the disgust response have homologues or analogs in other species. It is their entanglement that creates a uniquely human emotion. Moral disgust represents a further piece of evolutionary tinkering in which the emotion of disgust was co-opted to help enforce conformity with in-group norms.

Although competing explanations of the evolution of pride and shame are extant in the literature, a consensus is emerging. Behaviors homologous to those we associate with pride and shame are components of displays employed by nonhuman

primates (and other mammals) during the negotiation or affirmation of relative rank. We can label the emotions that underlie such displays as 'protopride' and 'protoshame.' In a competitive environment, the expression of protoshame signals the actor's acceptance of a subordinate position in a hierarchy. It functions to deflect aggression from the dominant party. The expression of protopride, in contrast, signals the actor's dominance. Importantly, protopride is a pleasant feeling, while protoshame is unpleasant. Daniel Fessler (1999) argues that protopride and protoshame were selected for in primates because they promoted dominance-seeking behaviors, which increased the chances of reproductive success. These emotions are the phylogenetic ancestors of pride and shame in human beings (Fessler, 1999, 2004). However, Jason A. Clark (2012) has argued that humans retain the ability to experience protopride and protoshame alongside their more sophisticated descendants, pride and shame.

Pride and shame are more cognitively complex than protopride and protoshame. They require that the organism has 'theory of mind' – the capacity to attribute mental states to other individuals. They also serve a different adaptive function in the relatively cooperative, nonhostile environments human beings inhabit. In such contexts, pride and shame are experienced in response to the actual or imagined assessment of an actor's behavior by an audience. If the assessment inspires the contempt or pity of the audience, the actor feels shame. If the assessment inspires the envy or admiration of the audience, the actor feels pride. In the cooperative context, then, pride and shame encourage the actor to seek the admiration and envy of others, which in turn encourages them to act in ways that support the well-being of the group (Fessler, 1999). In this way, these emotions inspire adherence to socially sanctioned norm-governed behavior.

There is broad agreement that the capacity to adhere to norms is an evolved capacity in humans that requires, among other things, the capacity for appropriate emotional responses. Whether this means that the capacity for morality has itself evolved is a matter of some controversy. Jesse Prinz (2007) is a prominent exponent of the view that morality has not evolved. He opposes nativists who think humans are born with a set of universal moral principles like *'Don't harm innocent people*.' However, most self-described moral nativists agree with Prinz that it is unlikely that universal moral judgments of this sort evolved. What such nativists do endorse is the more plausible view that the *capacity* to form moral judgments is the result of natural selection (Joyce, 2006). Evidence supporting nativism of this latter sort frequently appeals to the universality of moral systems in human cultures. All cultures have moralities, even if those cultures disagree about which universal moral principles are correct. Nativists also point to evidence that young children appear to recognize what is distinctive about moral rules (as opposed to merely conventional rules) without formal tutelage. Prinz (2007) argues that this latter piece of evidence fails to consider the rich resources of the learning environment. He suggests that the transgression of moral rules is punished more severely than the transgression of merely conventional rules. As a result, children learn to associate emotions like guilt and shame with the transgression of moral norms, and in this way become able to discern the distinctive character of moral judgments.

Jonathan Haidt and Craig Joseph (2007) have recently outlined a nativist explanation of the origins of five sets of moral concerns: harm, justice, loyalty, authority, and sanctity. Haidt and Joseph argue that humans have learning modules responsible for emotions whose appearance depends on the detection of moral patterns in the social world. They think that each learning module corresponds to one of the five sets of moral concerns, but that the specific content, and the relative importance, of each moral concern is modified by experience. Their work moves away from moral psychology's overarching focus on the moral concerns of modern, secular, liberal, and Western societies (namely, harm and justice). It advocates inclusion of the moral concerns of non-Western and traditional cultures and Western religious conservative culture (namely, loyalty, authority, and sanctity).

The dispute between nativists and nonnativists about the evolution of morality, like most nature/nurture disputes, is made more complex by the multiple ambiguities of the term 'innate' (Mameli and Bateson, 2006). A trait may be 'innate' in the sense of being designed by natural selection, but nevertheless depend on features of the normal developmental environment, such as normal parenting, if it is to develop. So even if some aspect of morality is not 'innate' in the sense that its development requires the right kind of environment, it may still be the result of adaptive evolution. Natural selection can also produce phenotypic plasticity, in which organisms develop a range of different traits depending on the particular environments in which they develop. So even if some aspect of morality is not 'innate' in the sense that it is part of a universal human nature, the range of features that develop in different environments may still be the result of adaptive evolution. Distinguishing the question of whether morality has been designed by natural selection from these and other alternative senses in which morality might be 'innate' is essential when assessing the evidence for the evolution of different aspects of morality and of the moral emotions. Haidt and Joseph try to finesse this problem by defining 'innate' with the apparently minimal condition of "organized, to some extent, in advance of experience" (2007: p. 367), but this still does not separate the phylogenetic issue of evolutionary design from the ontogenetic issue of the role of experience.

Conclusion

Theories of the evolution of emotion have an intellectual lineage stretching back to Darwin himself. The development of the field has reflected more general trends in the history of Darwinian approaches to mind and behavior. Important current issues include the number of separate, evolved emotions; the nature of the stimuli that produce evolved emotions; and a cluster of issues about the evolutionary function of emotional behaviors and their relationship to underlying emotional states, issues which are often discussed in terms of whether emotional behaviors should be primarily regarded as expressions or as signals. Perhaps the most significant recent development in the field is an upsurge of

work on the evolution of moral emotions. This article has substantial implications for ideas about the evolution of morality itself.

Abstract

In the past decades, in several scientific disciplines we observe growing interest in emotion – from neurobiology, philosophy, history, and anthropology to as far as sociology. In the course of the twentieth century, under the influence of a rationalist concept of man pushing through, the value of emotions had declined in the social sciences. Contrasting rationality and emotionality as mutually excluding attitudes looks back to a long history and has only recently increasingly been questioned. The development of this rationalist attitude is sketched in this article. In addition, the relationship between physiological aspects, cognitive appraisal, and emotion is described (most of all in reference to psychological literature and those of the neurosciences) and an overview of current sociology of emotions is given.

In the past decades, in several scientific disciplines we observe a growing interest in emotion. This covers a whole range – from neurobiology, philosophy, history, anthropology, as far as to sociology. If we consider the history of emotion research, it is conspicuous that over long periods emotions were considered the realm of individual disciplines (such as psychology) and were, thus, in tendency neglected by other disciplines (Scherke, 2009: 11–15). Only recently, an attitude has become more prevailing, which assumes that for the understanding of human emotions we need an interdisciplinary approach. In this article, we present some important steps of the historical development of emotion being a concept in the social sciences (sociology, in particular) – with a special focus also on the changing importance of this concept for various disciplines.

Already, the classical authors of sociology pay attention to human emotions, as has been shown in recent years by referring to the works of people such as Max Weber (1864–1920), Emile Durkheim (1858–1917), or Georg Simmel (1858–1918) (Kemper, 1990: 5; Williams and Bendelow, 1998: XV; Flam, 2000: 154). However, the analyses of the classical authors of sociology concerning the topic of emotions were not immediately continued. In the course of the twentieth century, emotions were gradually excluded from the sociological debate, which continued into the 1970s (Scherke, 2009: 291–294). Only after that time one can speak of sociology rediscovering the topic – most of all in the English-speaking countries (on the various trends of the special field of the sociology of emotions see Turner and Stets, 2005).

In the course of the twentieth century, under the influence of a rationalist concept of man pushing through, the value of emotions declined in debates of the social sciences. The development of this rationalist attitude shall be sketched here briefly. Contrasting rationality and emotionality as mutually excluding attitudes looks back into a long history and has only recently been questioned increasingly. For a structuring of the debate on rationality and emotionality, the division into three of the possible attitudes as suggested by Barbalet (Barbalet, 1998: 29) proves to be very useful: the *conventional approach*, which in the past few years has increasingly been questioned; the *critical approach* which since most recently is characterized, most of all, by the inclusion of neuroscientific insights and postulates a close connection of rationality and emotionality; and the *radical approach* which completely gives up on any distinction between emotionality and rationality.

Rationality and Emotionality

From a conventional point of view, rationality and emotionality are two separate fields of human 'being-in-the-world.' According to this approach, emotions are in most cases an obstacle for rational action. First roots of such a way of understanding emotions are found already in antiquity. The negative judgment of the Pre-Socratics, advised to avoid the stimulation of emotions, is also supported by Plato (fifth/fourth century BC), for example, although already he draws a differentiated, not exclusively negative, image of emotions and considers pleasure together with reason, an essential part of happiness in life. Also Aristotle (fourth century BC) does not strive for being completely liberated from emotions but considers the right measure a desirable virtue (Lanz, 1971: 89–95). Then, the rather negative view of emotions as unreasonable impulses that are to be avoided is found most of all among the representatives of the Stoa. While, for example, Zenon (fourth/third century BC) considers wrong judgments of reason the starting point for emotions which, however, he considers phenomena that must basically be distinguished from reason, for Chrysippos (third century BC) emotions cannot be separated from reason but must be judged on as exercising them in the wrong way. In the Middle Ages, this attitude is taken up again and sharpened, as far as asking in how far emotions are capable of influencing conscious decisions. Thomas Aquinas (1225–74) emphasizes the physical dimensions of emotion. As such, he says, emotions are neither good nor bad; if they are controlled by reason, they count among the virtues, if not, then they lead toward sin. Basically, they are not completely subject to the human will. The comprehensive way of understanding emotions, which in antiquity and the Middle Ages is still found to a certain degree – emotions both as suddenly triggered or long-time states of the soul and efforts by the soul – gradually becomes more differentiated in the debate of Modern Age, by more clearly distinguishing between the rather lasting desires of man and his spontaneous emotions. Also, the idea of body and soul being mostly one, which is still found in the writings of some ancient

authors and also in Thomas Aquinas, is then replaced by the idea of the two being strictly separated.

Thus, Barbalet describes the conventional understanding of the relation of rationality and emotionality by reaching back to René Descartes (1596–1650). Descartes' 'cogito ergo sum' makes reason the center of human existence, whereas now emotions are considered most of all by their relation to reason and by their possible destructive effects on it. The will, he states, must master the passionate impulses coming from the body. In this point of view emotions and reason are understood to be contradicting phenomena, in the context of which the realm which is associated with man's free will – that is, reason – is appreciated, whereas emotions must be suppressed as bodily phenomena that are obstacles for reason. However, when explaining Descartes' view of emotions it may not be overlooked that he dealt in very much detail with the physical processes of emotion. Thus, appreciating reason was not connected to neglecting (or lacking interest in) emotion. Also, we must note that the soul is capable, by imagining situations which contradict currently existing passions, of starting appropriate *physical* mechanisms, and thus of controlling unwanted passions. Often the perception of Descartes overlooked this fundamental connection of body and soul (which only allowed also for mastering the passions), thus one-sidedly emphasizing his explanation of the passions as phenomena that contradict reason. In the past centuries conventional view proved to be the predominant understanding of the relation of rationality and emotionality (despite the existence of other views) (Barbalet, 1998: 54–61).

In contrast to the conventional concept, the critical view of the relation of rationality and emotionality emphasizes that only emotions make cognition, that is, rational consideration, purposeful. Also this view considers emotion and reason as two different phenomena; however, one assumes a closer interaction of both. Also for this concept we find predecessors already in antiquity and the Middle Ages. In the eighteenth century, the Cartesian concept of man was criticized most of all by the Scottish moral philosophers who strived for a rehabilitation of man's senses and passions. David Hume (1711–76) assumed that passions control the will, thus directing human behavior toward a goal. Furthermore, already in Hume we find the basic idea of the radical approach, which is presented in the following, according to which rationality itself may be considered a certain kind of emotion. Thus, from the point of view of the critical approach emotions are necessary to direct reason, which may be of significance most of all in respect to a revision of modern Rational-Choice theories. By a kind of division of labor between the emotional and the rational components of human 'being-in-the-world' it becomes possible to define goals and then to try to achieve them by way of reasonable action. Often, humans are confronted with contradicting goals between which a rational decision is hardly possible. Furthermore, in many situations they have only insufficient information, which makes reasonable action even more difficult. In such cases emotions may contribute significantly to decision making, by allowing for a clear judgment on the various goals and for selecting one of them, despite lacking background information. This way they also guarantee long-term social cooperation – by avoiding egotistic, short-term goals. Most recently, most of all insights of the biosciences have produced evidence for the critical approach which have meanwhile also found response in the field of economics (Damasio, 1994; Barbalet, 1998: 39; Elster, 1998: 47–74; Fehr and Fischbacher, 2004). In contrast to the conventional understanding, which considers too much emotion an obstacle for rational decision making, *lack* of emotions is now seen as counterproductive for rational behavior.

The radical view assumes that rationality and emotionality are basically not different from each other, but that rationality itself may be considered a conglomerate of particular emotions.

As mentioned above, the idea of an inseparable connection between reason and emotion is already found in Chrysippos. Sometimes, this connection of reason and emotion is also found among the thinkers of Enlightenment, together with a positive judgment on the knowledge of the world guided by emotion. Such an idea is found in Alexander Gottlieb Baumgarten (1714–62), for example. For him, insight resulting from an emotional, aesthetic understanding of the world may be considered to be in analogy with reasonable insight (Franke and Oesterle, 1974: 83–86). Also, in the debate on so-called moral emotions, emotion is said to have a cognitive function in the widest sense. There, emotions become the actual bearer of human decision making and are thus attributed a degree of significance which is sometimes believed to be superior to reason-based insight, for example as described in the works of Anthony Ashley Cooper Shaftesbury (1671–1713) or in Francis Hutcheson (1694–1746). Also in Max Scheler's (1874–1928) phenomenology some cognitive achievements are based on such an emotional ground. Emotions are important most of all for concluding on values, and the thus resulting moral decisions (Scheler, 1954: 260–272). This independent relation to reality by way of emotions or feelings is crucial for Scheler's revaluation of emotion compared to reason.

We find evidence for the radical position also in David Hume and William James (1842–1910). Hume was of the opinion that spiritual activities carried out prudently and calmly are called reason. However, he said, this name hides the work of calm passions which, no less than violent passions, count among emotions (Barbalet, 1998: 31). Furthermore, James pointed out to the physical changes happening when experiencing certain emotions. In his opinion, man's spirit cannot be considered without these physical states. Insofar as rationality is characterized by certain physical sensations. According to James, the emotion of rationality is characterized most of all by being oriented at the present moment which does not seem to require further justification or explanation, thus allowing for focusing thought (James, 1956: 63–64). A 'feeling of rationality' provides security, thus guaranteeing the continuation of the action, which otherwise would not have happened. According to this view, rationality is just a special kind of emotional orientation toward the future (which may be described as being characterized by composure and calmness); however it cannot in principle be distinguished from other emotional orientations toward the future.

Body and Emotion

As sketched above, already philosophy in antiquity and the thinkers of Enlightenment as well as those of the nineteenth

century dealt with emotions. In the course of the differentiation of the system of sciences, which in the nineteenth century resulted in psychology being separated from philosophy, emotions were systematically dealt with in the context of this 'newly' developing discipline. In the course of the past 150 years psychology has assessed – sometimes by way of experiments – a variety of different theories on the question of how emotions are created. The following overview focuses on the question of which meaning has been attributed to physiological factors when it comes to emotional processes. Various points of view shall be sketched by way of some 'milestones' on the road to today's concept of emotions which is much influenced by the neurosciences, and thus by physiological factors. However, we have to take into account that this was not at all a linear process and even in psychology there exist theories that do not refer to physical aspects in a narrow sense.

There is, for example, the James–Lange theory that emphasized the significance of physiological experience for emotional feeling. At the end of the nineteenth century William James (like at about the same time as Carl Lange (1834–1900)) assumed that initially we never judge on a situation in a cognitive way before there happens an emotional reaction (we see a bear, recognize the danger, become afraid, and run away), but that it is our physiological experience that determines our emotions (we see a bear, run away and are thus afraid, i.e., we interpret our running away as a reaction of fear). Thus, the conscious experience of an emotion comes after the physiological processes. Often this was interpreted as stating that any emotion is characterized by a specific physiological signature (LeDoux, 2001: 48–51).

In the 1920s this assumption was taken up and modified by the Cannon–Bard theory. According to this theory, developed by Walter Cannon (1871–1945) and Philip Bard (1898–1977), it is only general conditions of agitation (due to reactions by the sympathetic nervous system, which are assumed to be consistent) which may become subject to a cognitive appraisal. Cannon and Bard assumed that physiological agitation and the conscious perception of an emotion happen parallel and that the consciously perceived emotional state is not a consequence of physical agitation only, as it was still assumed by James and Lange. The physical reactions, they stated, are most of all responsible for the intensity and urgency of a perceived emotion but do not determine its specific nature.

Then, in the course of the predominance of behaviorism in psychology, as far as into the 1950s, emotions were hardly discussed. This changed in the course of the 'cognitive revolution' which paid increasingly more attention to the conscious processing of information by the human mind. In contrast to the behaviorist stimulus–response model, man's mind was 'rehabilitated' and became once again a matter for psychology. However, as LeDoux criticizes, this sometimes happened by neglecting the physical (most of all neuronal) preconditions of the human information processing (LeDoux, 2001: 29, 58). For example, in the 1960s Stanley Schachter (1922–97) and Jerome Singer (1934–2010) joined the Cannon–Bard theory of the general state of agitation, however by enriching it by the thesis that apart from perceiving physical agitation also the perception of the actual environment influences the finally resulting emotion (Schachter and Singer, 1962). Schachter and Singer described in particular the social environment as being crucial for the kind of created emotions. According to this view, cognitive processes are thus responsible for the development of different emotional states. As Magda Arnold (1903–2002) found out in the 1960s, it is also cognitive appraisal that provides the starting point for the emotional process, after all. She made the triggers of these physical processes the focus of her considerations (Arnold, 1960). In the course of a process of cognitive appraisal, she said, the individual judges on his/her current (environmental) situation, and that is concerning the possible damage or benefit it may cause.

Arnold and other representatives of the appraisal theory assumed that those processes as being responsible for triggering an emotion are basically accessible to consciousness, which is why reports of patients based on introspection may be used as sources for the research of emotional processes. In contrast to this, LeDoux follows Robert Zajonc's (1923–2008) considerations, who, in the 1980s, had moved away from the long predominance of cognition and postulated a more complex relation of cognitive and emotional processes, for which most of all processes of unconscious information processing play an important role. Decisive for Zajonc's considerations were experiments during which test persons had developed preferences for stimuli that were offered only for a short time (and were thus not consciously perceived) (Zajonc, 1980). This unconscious information processing was the starting point for LeDoux's examinations (LeDoux, 2001: 58–69). Already, since the 1950s certain parts of the brain (the so-called limbic system) were considered the central switchboard of emotional perception. From LeDoux's point of view, not those parts of the brain which are called the limbic system are responsible for emotions, but there exists a complex process of processing of the incoming sensual information, in the course of which different physical (and thus also neuronal) systems are activated. For his work, LeDoux focuses on fear. The essential result, in short, is that there is so to speak a double process of information processing in the brain. Sensual perceptions reach the thalamus in the form of nerve impulses and from there go to the neocortex (where there happens cognitive assessment) and also to the amygdala (which controls physical reactions). In this context, those nerve impulses reaching the amygdala may sometimes already trigger physical reactions even before the sensual perceptions have been cognitively assessed. Thus, this approach enriches the cognitive appraisal theory, insofar as it offers an explanation also for the rapid, unconscious assessment of certain situations.

In the context of the debate on the emotional process, the concept of evolution has played an important role time and again – apart from the question of how physiology and cognition work together – that is, human emotions were analyzed in view of their functions as adjustment advantages (Turner, 2000: 19–21). Closely connected to these evolutionary considerations is also the idea of emotions finding universal expression. This assumption, which Charles Darwin (1809–82) had already expressed in 1872, was taken up by Paul Ekman in the 1960s. He gave evidence to it by several culture-comparative studies, in the course of which, however, it also became clear that there are culture-specific rules of presentation which demand the open expression or hiding of certain emotions (Ekman, 1984). Linked to the debate on the cross-cultural status of emotions and their evolutionary functions is also the idea of the existence of certain basic emotions or primary emotions, the opinions concerning

their kind and number being widely apart still today (Ulich and Mayring, 1992: 36–37, 132–133).

Since the 1960s, the complexity of the human emotional process, which includes biological, social, and cultural components, has also produced system–theory-oriented theories of emotion – such as in Carroll E. Izard or Silvan S. Tomkins (Tomkins, 1962; Izard, 1971) – which attempt descriptions of the interaction of these different components. More recently, the analysis of neuronal processes has played an important role also for system–theory-oriented theories of emotions.

In contrast to the debates of the 1960s and 1970s, which were characterized by the cognitive sciences, currently the physical dimension of the emotional process is in the fore of scientific attention (most of all in the neurosciences) again. However, since the 1970s also a 'sociology of emotions' has established as a special field within sociology, trying to shed light on the significance of social factors for the emotional process and to find out about their interaction with other factors (such as physiological ones).

Sociology of Emotions

Two main lines can be distinguished within the *sociology of emotions*: one line making the *social development* of emotions a topic of discussion, and the other investigating the *social effects* of emotions (Scherke, 2009: 58–62). This is only a very rough structure which, however, is suitable for illustrating the basic direction of studies.

Authors considering them to be characterized or changed by social structures analyze emotions for the way in which they are created. In this context, emotions are not only considered something biologically predetermined, but also as a phenomenon that is essentially (co)influenced by the social and/or cultural environment (like already Schachter/Singer have shown). The question about the 'nature' of emotions, that is, about their fundamental characteristics and ways of appearance, is in the fore for these studies. This is a topic also dealt with by other disciplines, which is why this field shows a number of interdisciplinary interfaces.

However, in the context of the *sociology of emotions* we also find studies analyzing the effect of emotions on social situations. According to this approach, emotions are assumed to be mostly given (without any implicit decision about their biological and/or social nature). Here the question of how emotions are created is postponed, and instead one discusses the effects of emotions on the structuring of social contexts. Basically, this approach also shows interfaces with other disciplines; however, in terms of research practice they may be more neglected to a certain degree than it is the case with the former approach. In other words, new bioscientific insights concerning the way in which emotions are created do not necessarily result in a revision of sociological explanations for the social effects of emotional behavior. The social consequences of emotions may, so to speak, be considered to belong to tasks of sociology in the *stricter* sense.

Among the approaches dealing with how emotions are characterized by social structures and interactions we may distinguish a positivist and a constructivist approach. Between these two there was an extensive debate in the Anglo-Saxon countries in the 1970s and 1980s. For both approaches the macro-level is in the fore. The constructivist approach refers to the macro-level by way of normative feeling rules regulating the way in which emotions are expressed, thus serving as a link between the social or cultural context (as well as its historical development) and the emotions of the individuals. By way of interactions between participants there occur negotiations about which emotions are felt or may be felt in each case. Aspects of social control play an important role for this modulation of emotions (in the form of sanctions by others or of internalized self-control learned in the course of socialization). It is the individuals who create and redesign emotions – in the sense of emotion work or emotion management (Hochschild, 1983) – adjusted to the respective social context. As has been shown also by recent ethnological studies, the respective cultural context is quite decisive for the way in which emotions are expressed. Furthermore, it must be taken into consideration that feeling rules change in the course of history. Quite a number of studies deal with the development or change of emotional concepts – such as the concept of Romantic love which is mostly a 'product' of the nineteenth century and has essentially contributed to the way in which partner relationships have been lived since then (Illouz, 1997).

The positivist approach assumes that emotions are more or less directly created by social–structural positions or relations of interaction partners, without considering processes of emotion management. Partly, most of all in Theodore D. Kemper, this idea also implies that social–structural positions, physiological mechanisms, and perceived emotions are closely linked (Kemper, 1978). Also, this approach refers predominantly to the micro-level, by sketching in a model possible interaction situations between two individuals or among small groups concerning their power and status relations and by analyzing them for their emotional consequences. However, also for this approach we may state a reference to the meso- or macro-level, as the social position of social groups (thus also a model of social segregation) can be included into the analysis.

Those approaches as analyzing the influence of emotions on the social plane can be further divided into those discussing emotional states as general preconditions for human behavior (and thus also social behavior) and those dealing with the various social consequences triggered by concrete emotions. From the point of view of the interpretative approach within the *sociology of emotions*, emotions are attributed a considerable role for the construction of reality. Emotions influence social situations in a way as to contributing to a (mostly nonverbal) structuring of social situations, by reducing the range of possible meanings in the context of interactions. Thus, emotions are part of the unquestioned preconditions for social situations, thus allowing for everyday processes. By way of facial gestures – and emotions are expressed most of all by facial expressions – fundamental attitudes toward the world and the current situation are communicated, thus reducing the possible leeway for interpretation, as interactions are always connected to a certain degree of insecurity. In other words, a sentence which is said with a smile is attributed a different meaning than the same sentence expressed in an angry voice and by the appropriate facial expression. Without analyzing the content in detail, the respective interaction partner will already react to the emotional tone of the message, which will steer the

course of the interaction further into a certain direction. In so far, emotions and the emotional way of creating meaning can contribute to behavioral certainty, and thus to efficient acting in the context of interaction. Among the concrete emotions whose effects on social behavior or social structures have been analyzed there count for example trust (Barbalet, 1998: 84–94), fear (Flam, 2000: 54–65), and shame (Scheff, 1990: 284–289). According to Collins, apart from short-term emotions (e.g., fear or anger) it is most of all long-term emotions or emotional moods that influence social structures (Collins, 2004: 3–25). These long-term emotions are created in the context of rituals. For this, there must be the direct physical encounter of at least two humans whose attention is directed to the same object or at a common activity and who finally become aware of this common direction. By way of directing their attention at the same object, the actors are capable of adjusting their emotional moods. Here, Collins refers to the state of collective effervescence as a result of group rituals which was already emphasized by Emile Durkheim. Collins speaks of rhythmic entertainment, by which he means the adjustment of the participants' moods due to physiological processes in the context of a successful ritual. If this adjustment to a common mood succeeds, not only the emotions of each individual are increased but there also results group solidarity. For example at burials, where the individual actors express emotions of mourning, the common ritual may not only increase the individual's emotions of mourning, they may also create or consolidate solidarity among the mourners. Thus, the long-term result of the interactions of a ritual is on the one hand the revaluation of group solidarity (including the positive charging of group symbols and group-related norms) and on the other hand an increase of the individuals' so-called emotional energy.

Among the *sociology of emotions* there exist a number of refined theoretical concepts and meanwhile a multitude of empirical studies on a variety of social fields (from social movements, politics, the Internet, as far as to business enterprises; Flam and King, 2005; Wettergren and Sieben, 2010; Pixley, 2012; Demertzis, 2013; Benski and Fisher, 2014). There has been a slight tendency to emphasize the social constructedness of emotions in order to overcome the predominance of psychology (or nowadays of the neurosciences) in emotions research and to make emotions a research topic for sociology again. This has led to a neglect of bodily aspects in tendency (with some exceptions like Kemper). This gap has to be closed by future research, which should also strive for a stronger connection of theoretical and empirical approaches.

Abstract

Emotions can usefully be defined as states produced by rewards and punishers. Emotions prepare the body for action, but perhaps their most important function is to enable appropriate actions to be produced to stimuli and events that are rewards or punishers. The rewarding stimuli or events can be innate (gene-specified) or learned. The orbitofrontal cortex is especially important in emotion, because it represents rewards and punishers, and learns about which previously neutral stimuli are associated with rewards and punishers, and when these associations change. For this fundamental reason, parts of the brain such as the orbitofrontal cortex are important in social and emotional behavior. The anterior cingulate cortex receives from the orbitofrontal cortex and is involved in learning goal-directed actions to obtain reward or avoid punishers. The amygdala is an evolutionarily older system also involved in some responses to emotional stimuli.

In order to provide a fundamental basis for understanding the neural basis of emotion, it is useful to have a clear view of the events that give rise to emotions and the functions of emotion, for these help to define the input systems in the brain involved in producing emotions, and the output systems in the brain that are involved in expressing emotion. With this basis, developed fully by Rolls (2005, 2013a, 2014), the neural systems that underlie emotions are then considered.

The Events that Give Rise to Emotions

Emotions can usefully be defined as states produced by rewards and punishers. Rewards are stimuli for which an animal (including humans) will work, and punishers are stimuli that an animal will work to escape from or avoid. Rewards and punishers are instrumental reinforcers in that they alter the probability of behavior. Some stimuli are unlearned or primary reinforcers (e.g., the taste of food if the animal is hungry, or pain). Other stimuli may become reinforcing by learning, because of their association with such primary reinforcers, thereby becoming 'secondary reinforcers.' For example, fear is an emotional state which might be produced by a sound (the conditioned stimulus) that has previously been associated with a painful stimulus (the primary reinforcer).

The different emotions can be described and classified according to whether the reinforcer is positive or negative, and by the reinforcement contingency. An outline of such a classification scheme, which applies to each reinforcer, is shown in Figure 1.

The operation of the following factors enables a very wide range of different emotions to be described:

1. The reinforcement contingency (see Figure 1).
2. The intensity of the reinforcer (see Figure 1).
3. Any environmental stimulus might have a number of different reinforcement associations. For example, a stimulus might be associated both with the presentation of a reward and of a punishment, allowing states such as conflict and guilt to arise.
4. Emotions elicited by stimuli associated with different primary reinforcers will be different.
5. Emotions elicited by different secondary reinforcing stimuli will be different from each other (even if the primary reinforcer is similar).
6. The emotion elicited can depend on whether an active or passive behavioral response is possible. For example, if an active behavioral response can occur to the omission of a previously rewarded stimulus, then anger might be produced, but if only passive behavior is possible, then sadness, depression, or grief might occur.

By combining these six factors, it is possible to account for a very wide range of emotions. It is also worth noting that

1. emotions can be produced just as much by the recall of reinforcing events as by external reinforcing stimuli;
2. cognitive processing (whether conscious or not) is important in many emotions, for very complex cognitive processing may be required to determine whether environmental events are reinforcing or not;
3. emotions normally consist of cognitive processing which determines the reinforcing valence of the stimulus, and an elicited mood change if the valence is positive or negative;
4. and that stability of mood implies that absolute levels of reinforcement must be represented over moderately long time spans by the firing of mood-related neurons, a difficult operation which may contribute to 'spontaneous' mood swings, depression which occurs without a clear external cause, and the multiplicity of hormonal and transmitter systems which seem to be involved in the control of mood.

The Functions of Emotion

The functions of emotion can be summarized as follows.

1. The *elicitation of autonomic responses* (e.g., a change in heart rate) *and endocrine responses* (e.g., the release of adrenaline). These prepare the body for action.
2. *Flexibility of behavioral responses to reinforcing stimuli.* Emotional (and motivational) states allow a simple interface between sensory inputs and motor outputs. The new understanding is that some genes specify which stimuli are rewarding and punishing, and these stimuli are

Figure 1 Some of the emotions associated with different reinforcement contingencies are indicated. Intensity increases away from the center of the diagram, on a continuous scale. The classification scheme created by the different reinforcement contingencies consists of (1) the presentation of a positive reinforcer (S+), (2) the presentation of a negative reinforcer (S−), (3) the omission of a positive reinforcer (S+) or the termination of a positive reinforcer (S+ !), and (4) the omission of a negative reinforcer (S−) or the termination of a negative reinforcer (S− !). It should be understood that each different reinforcer will produce different emotional states: this diagram just summarizes the types of emotion that may be elicited by different contingencies, but the actual emotions will be different for each reinforcer.

the goals for flexible actions. For example, genes specify that strong somatosensory stimuli produce a state of pain which animals (including humans) are built to perform actions to avoid or escape. The state produced by the painful stimulus is an emotional state which has the adaptive function of identifying and maintaining the goal for an action. This is an efficient design, for the genes need only specify the goals for actions, and not the actions themselves, so that the actions can be selected flexibly to meet the goals. It would be very inflexible and inefficient for the genes to specify actions themselves. In this way, emotions provide an efficient interface between sensory systems and actions. The hypothesis is that our emotions correspond to the goal-specifying states arising from stimuli that genes have found it adaptive and possible to specify. Rolls (2014) provides a table of some of the primary reinforcers that genes appear to specify, and thus an idea of how a wide range of different emotions have evolved because of their adaptive implications. This approach provides a fundamental approach to understanding emotions in terms of their evolutionary adaptive value.

3. Emotion is *motivating*. For example, fear learned by stimulus–reinforcement association formation provides the motivation for actions performed to avoid noxious stimuli. Rolls' evolutionary approach provides a unifying theory of motivation and emotion, for motivational states occur when we try to obtain (gene-specified) goals, and emotional states occur when those goals are, or are not, obtained. The goal in both cases is defined by the same gene-based reward and punishment systems in the brain.
4. *Communication*. For example, monkeys may communicate their emotional state to others, by making an open-mouth threat to indicate the extent to which they are willing to compete for resources, and this may influence the behavior of other animals. This aspect of emotion was that emphasized by Darwin (1872).
5. *Social bonding*. Examples are the emotions associated with the attachment of the parents to their young, and the attachment of the young to their parents.
6. The current mood state can affect the *cognitive evaluation of events or memories* (Pessoa, 2010; McIntyre et al., 2012; Rolls, 2013b), and this may have the function of facilitating continuity in the interpretation of the reinforcing value of events in the environment.
7. Emotion may facilitate the *storage of memories* (Rolls, 2008, 2014). One way in which this occurs is that episodic memory (i.e., one's memory of particular episodes) is facilitated by emotional states. This may be advantageous in that storing many details of the prevailing situation when a strong reinforcer is delivered may be useful in generating appropriate behavior in situations with some similarities in the future. A second way is that the current emotional state may be stored with episodic memories,

providing a mechanism for the current emotional state to affect which memories are recalled. A third way in which emotion may affect the storage of memories is by guiding the cerebral cortex in the representations of the world which are set up. For example, in the visual system, it may be useful to build perceptual representations or analyzers that are different from each other if they are associated with different reinforcers, and it may be less likely to build them if they have no association with reinforcement.

8. Another function of emotion is that by enduring for minutes or longer after a reinforcing stimulus has occurred, it may help to produce *persistent and continuing motivation and direction of behavior*, to help achieve a goal or goals.
9. Emotion may trigger the *recall of memories* stored in neocortical representations. Amygdala backprojections to the cortex could perform this for emotion in a way analogous to that in which the hippocampus could implement the retrieval in the neocortex of recent (episodic) memories (Rolls, 2008).
10. Rewards and punishers, and the emotional states they produce, are represented on a common scale that facilitates choices and decisions between different rewards, and between actions and their costs to obtain these rewards (Grabenhorst and Rolls, 2011; Rolls, 2014).

Brain Mechanisms of Emotion

Overview

Animals are built with neural systems that enable them to evaluate which environmental stimuli, whether learned or not, are rewarding and punishing, that is will produce emotions and will be worked for or avoided. Sensory stimuli are normally processed through several stages of cortical processing to produce a sensory representation of the object before emotional valence is decoded. For example, in the taste system, taste is analyzed in primates to provide a representation of what the taste is in the primary taste cortex, and this representation is independent of the reward value of the taste in that it is not affected by hunger. In the secondary taste cortex, in the orbitofrontal region (see **Figure 2**), the reward value of the taste is represented, in that neurons only respond to the taste if the primate is hungry (Rolls, 2012a). In another example, in the visual system representations of objects which are view-, position- and size-invariant are produced in the inferior temporal visual cortex after many stages of cortical processing, and these representations are independent of the emotional valence of the object (Rolls, 2012b). Then in structures such as the orbitofrontal cortex and amygdala, which receive from the inferior temporal visual cortex, associations are learned between the objects and the primary reinforcers associated with them, by the process of stimulus–reinforcement association learning. In the orbitofrontal cortex and amygdala, emotional states are thus represented (Rolls, 2014).

Consistent with this, electrical stimulation of the orbitofrontal cortex and amygdala is rewarding, and damage to these structures affects emotional behavior by affecting stimulus–reinforcement association learning. These brain regions influence the selection of behavioral actions through brain systems such as the ventral striatum and other parts of the basal ganglia (Rolls, 2005).

The Amygdala

The amygdala receives information about primary reinforcers (such as taste and touch), and also information about visual and auditory stimuli from higher cortical areas (such as the inferior temporal cortex) that can be associated by learning with primary reinforcers (**Figure 2**). Bilateral removal of the amygdala in monkeys produces tameness, a lack of emotional responsiveness, the excessive examination of objects, often with the mouth, and the eating of previously rejected items such as meat (the Kluver-Bucy syndrome). In analyses of the bases of these behavioral changes, it has been observed that there are deficits in learning to associate stimuli with primary reinforcement, including both punishments and rewards. The association learning deficit is present when the associations must be learned from a previously neutral stimulus (e.g., the sight of an object) to a primary reinforcing stimulus (such as the taste of food).

Further evidence linking the amygdala to reinforcement mechanisms is that monkeys will work in order to obtain electrical stimulation of the amygdala, that single neurons in the amygdala are activated by brain-stimulation reward of a number of different sites, and that some amygdala neurons respond mainly to rewarding stimuli, and others to punishing stimuli (Rolls, 2014). The association learning in the amygdala may be implemented by associatively modifiable synapses from visual and auditory neurons on to neurons receiving inputs from taste, olfactory or somatosensory primary reinforcers (LeDoux and Damasio, 2013). Consistent with this, at least one type of associative learning in the amygdala can be blocked by local application to the amygdala of an *N*-methyl-D-aspartate (NMDA) receptor blocker, which blocks long-term potentiation, which is a model of the synaptic changes that underlie learning (Davis, 2006). The amygdala is involved in some conditioned responses to fear, including startle, freezing, and autonomic responses (Phelps, 2006; LeDoux and Damasio, 2013).

An interesting group of neurons in the amygdala (in, for example, the basal accessory nucleus) responds primarily to faces (Leonard et al., 1985). They are probably part of a system which has evolved for the rapid and reliable identification of individuals from their faces, and of facial expressions, because of the importance of this in primate social behavior. Consistent with this, activation of the human amygdala can be produced in neuroimaging studies by some face expressions, and lesions of the human amygdala may cause difficulty in the identification of some face expressions.

The Orbitofrontal Cortex

The orbitofrontal cortex receives inputs from the inferior temporal visual cortex and superior temporal auditory cortex; from the primary taste cortex and the primary olfactory (pyriform) cortex (see **Figure 2**); from the amygdala, and from the midbrain dopamine neurons. Damage to the caudal orbitofrontal cortex in the monkey produces emotional changes.

Figure 2 Schematic diagram showing some of the connections of the taste, olfactory, somatosensory, and visual pathways in the brain. V1, primary visual (striate) cortex; V2 and V4, further cortical visual areas. PFC, prefrontal cortex. VPL, ventro-postero-lateral nucleus of the thalamus, which conveys somatosensory information to the primary somatosensory cortex (areas 1, 2 and 3). VPMpc, ventro-postero-medial nucleus pars parvocellularis of the thalamus, which conveys taste information to the primary taste cortex. Pregen Cing, pregenual cingulate cortex. For purposes of description, the stages can be described as Tier 1, representing what object is present independently of reward value; Tier 2 in which reward value is represented; and Tier 3 in which decisions between stimuli of different values are taken, and in which value is interfaced to behavioral output systems.

These include decreased aggression to humans and to stimuli such as a snake and a doll, and a reduced tendency to reject foods such as meat. These changes may be related to a failure to react normally to and learn from nonreward in a number of different situations. This failure is evident as a tendency to respond when responses are inappropriate, for example, no longer rewarded.

For example, monkeys with orbitofrontal cortex damage are impaired on Go/NoGo task performance (in which they should make a response to one stimulus to obtain a reward, and should not make a response to another stimulus in order to avoid a punishment), in that they Go on the NoGo trials. They are also impaired in an object-reversal task in that they respond to the object which was formerly rewarded with food. They are also impaired in extinction in that they continue to respond to an object which is no longer rewarded. Further, the visual discrimination learning deficit shown by monkeys with orbitofrontal cortex damage, may

be due to the tendency of these monkeys not to withhold responses to nonrewarded stimuli.

The primate orbitofrontal cortex contains neurons which respond to the reward value of taste (a primary reinforcer), in that they only respond to the taste of food when hunger is present (which is when food is rewarding). It also contains neurons which learn to respond to visual stimuli associated with a primary reward such as taste, and which reverse their responses to another visual stimulus in one trial when the rewards and punishers available from those visual stimuli reverse. Further, these visual responses reflect reward, in that feeding the monkey to satiety reduces the responses of these neurons to zero. Moreover, in part of this orbitofrontal region, some neurons combine taste and olfactory inputs, in that they are bimodal, and are in 40% of cases affected by olfactory-to-taste association learning and by feeding the monkey to satiety, which reduces the reward value. In addition, some neurons in the primate orbitofrontal cortex respond to the sight of faces. These neurons are likely to be involved in learning which emotional responses are currently appropriate to particular individuals, and in making appropriate emotional responses given the face expression.

It has been found that another class of neurons in the orbitofrontal cortex of the monkey responds in certain non-reward situations (Thorpe et al., 1983). For example, some neurons respond in extinction, immediately after a lick had been made to a visual stimulus which had previously been associated with fruit juice reward, and other neurons responded in a reversal task, immediately after the monkey had responded to the previously rewarded visual stimulus, but had obtained punishment rather than reward. Another class of orbitofrontal neuron responded to particular visual stimuli only if they were associated with reward, and these neurons showed one trial stimulus–reinforcement association reversal. Another class of neuron conveyed information about whether a reward had been given, responding, for example, to the taste of sucrose, or for other neurons of saline.

These types of information may be represented in the responses of orbitofrontal neurons because they are part of a mechanism which evaluates whether a reward is expected, and generates a mismatch (evident as a firing of the nonreward neurons) if reward is not obtained when it is expected (Rolls, 2014). These neuronal responses provide further evidence that the orbitofrontal cortex is involved in emotional responses, particularly when these involve correcting previously learned reinforcement contingencies, in situations which include those usually described as involving frustration.

It is of interest and potential clinical importance that a number of the symptoms of frontal lobe damage in humans appear to be related to this type of function: altering behavior when stimulus–reinforcement associations alter, as described next. Thus, humans with frontal lobe damage can show impairments in a number of tasks in which an alteration of behavioral strategy is required in response to a change in environmental reinforcement contingencies (Rolls et al., 1994). Some of the personality changes that can follow frontal lobe damage may be related to a similar type of dysfunction. For example, the euphoria, irresponsibility, lack of affect, and lack of concern for the present or future which can follow frontal lobe damage may also be related to a dysfunction in altering behavior appropriately in response to a change in reinforcement contingencies. At one time, following a report by Moniz (1936), prefrontal lobotomies or leucotomies (cutting white matter) were performed in humans to attempt to alleviate a variety of problems, and although irrational anxiety or emotional outbursts were sometimes controlled, intellectual deficits and other side effects were often apparent (Valenstein, 1973). Thus these operations have been essentially discontinued.

To investigate the possible significance of face-related inputs to orbitofrontal visual neurons described above, the responses to faces that were made by patients with orbitofrontal damage produced by pathology or trauma were tested. Impairments in the identification of facial and vocal emotional expression were demonstrated in a group of patients with ventral frontal lobe damage who had socially inappropriate behavior (Hornak et al., 1996). The expression identification impairments could occur independently of perceptual impairments in facial recognition, voice discrimination, or environmental sound recognition. Thus the orbitofrontal cortex in humans appears to be important not only in the rapid relearning of stimulus–reinforcement associations, but also in representing some of the stimuli, such as face expression, which provide reinforcing information. Consistent with this, neuroimaging studies in humans are showing representations which reflect the pleasantness of the taste and smell of food, the pleasantness of touch, and also of quite abstract rewards and punishers such as winning or losing money (O'Doherty et al., 2001; Grabenhorst and Rolls, 2011).

The behavioral selection system must deal with many competing rewards, goals, and priorities. This selection process must be capable of responding to many different types of reward decoded in different brain systems that have evolved at different times, even including the use, in humans, of a language system to enable long-term plans to be made. These many different brain systems, some involving the implicit (unconscious) evaluation of rewards, and others explicit, verbal, conscious, evaluation of rewards and planned long-term goals, must all enter into the selector of behavior (Rolls, 2014). Although poorly understood, the issue of emotional feelings is part of the much larger problem of consciousness, and may involve the capacity to have thoughts about thoughts, that is higher order thoughts (Rolls, 2012c).

Abstract

Emotions evolved to serve our need to communicate quickly and efficiently. Expressions serve as symptoms of our internal states, a signal appealing to others for action, and a symbol to convey information about an event. Expression produces outwardly visible cues interpreted by perceivers for their valuable information. Expression and perception is largely automatic, yet also results from norms in expressing and perceiving emotions. Although expressions may have originated from reflexive actions, they have evolved into a complicated system providing information about other people's reactions, attitudes, and likely behaviors. Reading these messages confers an advantage for interpersonal interactions.

The human experience is characterized by interaction with others. Above and beyond verbal communication, communicating via emotion serves as a quick and efficient means to coordinate social action by conveying information that provides insight into others' internal states. Humans are uniquely equipped to display emotional expressions, via highly developed facial and vocal structures, body language, and artifacts such as written communication, music, and art. Likewise, humans are well equipped to perceive these emotional expressions, and those who can do so effectively have an advantage in their social lives and even work lives.

We begin by stepping back from emotional expression and perception to discuss more broadly the emotion process, which is responsible for the emotional experience that typically sets expression and perception into motion. We discuss theoretical perspectives and empirical findings regarding their functions, individual differences, and deliberate regulatory processes. We then discuss the concept of emotional contagion, whereby people 'catch' each other's emotions in a complex interplay between expression and perception, as well as discuss cultural differences.

The Emotion Process

The antecedent to expressing an emotion is a combination of emotional experience and deliberate attempts to manipulate expressions for strategic purposes. We summarize the two major theoretical perspectives on emotional experience.

Although intuition may suggest emotions arise irrationally, evidence shows that emotions arise out of an orderly and clearly sequenced process (Frijda, 1986; Smith and Lazarus, 1990). The most common scientific definition of emotion is that they are psychological and physiological reactions to the stimuli that people observe in the world around them – with stimuli including other people, events, internal thoughts, written messages, music, and works of art, to name a few (Frijda, 1988).

This means emotions are about *something* – something that catches our attention, even if we cannot immediately identify its source. Major theorists argue that we continually and automatically engage in a process called cognitive appraisal (Frijda, 1986; Smith and Lazarus, 1990). Cognitive appraisal involves asking a series of questions in an ordered checklist to evaluate any noteworthy stimulus (e.g., Frijda, 2007; Scherer, 1988; Smith and Ellsworth, 1985). Although there are slightly differing models, most include at least these five dimensions, among others: (1) *valence*, also called *pleasantness*, which is the extent to which the stimulus is positive, negative, or neutral – e.g., distinguishing happiness from sadness; (2) *novelty*, which is the extent to which the stimulus is familiar versus unfamiliar – e.g., distinguishing a positive surprise from serenity; (3) *goal obstruction*, or the extent to which the stimulus indicates that there is a concern in reaching one's goals – e.g., distinguishing challenge from enjoyment; (4) *control*, or an evaluation of whether the stimulus is controllable by the self, another person, or no one – e.g., distinguishing pride from anger from sadness; and (5) *fairness*, also called *norms*, or the extent to which the stimulus is consistent with social or personal standards – e.g., distinguishing contempt from irritation. The pattern of evaluations acts like a formula to determine what emotion we should feel (see **Table 1** for examples). For example, the dimension of control distinguishes many related emotions, particularly negative emotions – e.g., if a team project gets canceled, then a sense of personal responsibility over the cancellation is associated with guilt or shame,

Table 1 Dimensions of emotional appraisal

	Pleasantness	*Novelty*	*Goal obstruction*	*Control*	*Fairness*
Happiness	High	High	No		High
Sad	Low	Low	Yes	No one	
Angry	Low	High	Yes	Another person	Low
Fear	Low	High	Yes	Another person or no one	
Surprise		High			
Serenity	High	Low			
Disgust	Low				
Guilt	Low		Yes	Oneself	Low
Pride	High		No	Oneself	High
Relief	High		No

others' influence over the cancellation is associated with anger, and no one being responsible is associated with sadness or fear.

In describing this cognitive appraisal process, we emphasize that the tight mapping between appraisal dimensions and emotional experience creates opportunities for communication – through emotional expression and perception. In a process called *backtracking* (Elfenbein, 2007; Frijda, 2007), witnessing emotional displays gives us information because it allows us to step back and infer how other people appraise their situations. Even when emotional displays are strategically manipulated, backtracking provides useful information because it allows us to infer what expresser would like us to believe.

For balance, we note that there has been controversy between the *basic emotions* approach that is described here versus the *circumplex model* of emotion (Barrett and Russell, 1999). According to the circumplex model, our internal experience consists only of the pleasantness dimension of appraisal plus a sense of intensity level – and that the remainder of the appraisal process described above is a social construction. Because these two competing perspectives concern internal processes, our discussion of outward expressions can be consistent with either of these models.

This description of the appraisal process is intended to set the stage as context for discussing the expression and recognition of emotional displays. One does not only experience emotions based on these appraisals, but conveys these appraisals as information to others.

Expression of Emotion

Functions of Emotional Expression

Emotional experience creates urges that need to be released or contained. The first type of urge is to physical action; the root of the word emotion comes from the Latin word for motion. Each distinct emotion is related to specific *action tendencies* (Frijda, 1986), which are psychological and physiological responses that ready the individual to respond adaptively to the most pressing issues in their environments (Cosmides and Tooby, 2000; Frijda, 1986; Scherer et al., 2013). For example, happiness promotes social bonding, anger leads us to address problems in a relationship, and contempt leads us to reinforce a social hierarchy. The *social functional* perspective on emotion argues that these action tendencies serve functions in promoting group living (Morris and Keltner, 2000). Even if an emotion does not appear functional at every instance, it remains available in the repertoire because in some cases it helps social groups, like family units, to thrive or even simply remain intact. The second type of urge created by emotional experience is emotionally expressive behavior.

Why do we express our emotions? The Organon model (Bühler, 1934), summarized in **Table 2**, articulates three distinct functions: (1) *symptoms* convey the authentic internal experience of a speaker, which provides information to others about their states, intentions, attitudes, and likely future behaviors; (2) *signals* convey requests for actions from other people; and (3) *symbols* convey information about an event or object, in the way that spoken language represents our thoughts and environment. Although there is debate about the extent to which affective display is involuntary (i.e., symptoms, called *push factors*) or deliberate communication (i.e., signals and symbols, also called *pull factors*) (Ekman, 1971; Fridlund, 1994; Parkinson, 2005; Russell, 1994), these three functions are not meant to compete with each other. All three are valid reasons for emotional expression, and each of the three can be used singly or in combination – e.g., a wince can result from pain, can elicit helpful responses from those nearby, and can warn others to stay away from a dangerous situation (Singer et al., 2004). Separate psychological processes appear to distinguish push versus pull processes, which use separate neuroanatomical pathways guided by different tracts of facial nerves (Rinn, 1984).

Research and theorizing about emotional expression has been most common for the function of symptom; indeed, Ekman's (1971) influential *neurocultural theory* argues that our facial expressions are authentic readouts of emotional experience unless we are paying conscious attention to managing our faces. Even taking a less extreme perspective, it is clear that emotion displays are generated quickly and often without our awareness, which makes them an efficient form of communicating (e.g., Shariff and Tracy, 2011).

The signal function of emotion has also been an active focus of academic work, in terms of the social functions of emotion that lead emotional displays to induce reactions from others (Fridlund, 1994; Keltner and Haidt, 1999). By eliciting actions from others, emotions help to enhance the coordination of social groups. Positive expressions encourage others to

Table 2 The Organon model of interpersonal communication

Function	*Definition*	*Examples through emotional expression*
Symptom	Conveying the internal state of the expresser. Conveys emotions, intentions, and attitudes.	Sincere and automatic displays include an embarrassed blush when slipping on a banana peel, a surprised gasp when witnessing a car accident, and a joyful shriek when hearing good news.
Signal	Conveying an appeal to the observer that requests an action from them.	Deliberate appeals include a look of fear that begs for help, a look of anger that commands to stop, and a display of shame that tells others a punishment is no longer needed.
Symbol	Representing an object or event.	Deliberate communication of cognitive appraisal includes a scowl to show displeasure, a look of pride to convey who won the contest, or a smile to assure that a large animal is actually friendly.

continue their actions, whereas negative expressions serve as deterrence (Blair, 2003).

Relatively little work has been done on the symbolic function of emotional expressions. Laukka and Elfenbein (2012) found that appraisal dimensions can be inferred from listening to the acoustical cues posed by professional actors through their voice. As such, we can backtrack from emotional expressions and thereby reveal information about how the expresser evaluated their situation.

Modes of Emotional Expression

Humans are uniquely equipped to express a variety of emotions, having the specialized neural circuitry and muscular structures that allow for a range of expressions that stand unrivaled compared to other species (Burrows, 2008; LeDoux, 2012). Initially, emotional expressions may have been adaptive in readying the physiological systems to react to stimuli that have survival implications such as a fear response that facilitates heightened sensitivity of the sensory organs (Susskind and Anderson, 2008). These simple reflexes produced reliable signals that conveyed valuable information to others, and over time, began to be used deliberately (Russell et al., 2003) and evolved to communicate social and abstract concepts (Blair, 2003; Shariff and Tracy, 2011).

Emotional expression takes on many forms. First, push factors create outwardly observable cues. Long-standing theories point out that emotions are composed of both subjective feeling states and physiological responses (Darwin, 1872; James, 1884). Physiological markers of emotion experience include facial expressions, nonverbal components of vocal expressions, galvanic skin response, respiration, heart rates, bodily posture, and muscular movement (Banse and Scherer, 1996; Barrett et al., 2011; DePaulo and Friedman, 1998; Ekman and Rosenberg, 2005). Any of these changes can provide visible cues to others, even if they were not necessarily meant for an audience. Second, we evolved pull factors via the ability to manipulate the most outwardly visible of nonverbal cues, namely facial expressions, vocal tone, and body posture. Facial expressions are the most salient mode of expressions for humans, especially because humans are uniquely equipped with the complex facial muscular structure that can produce many differentiated emotional expressions. Perhaps for this reason, the bulk of research on emotional expression has focused on the face (Russell et al., 2003). However, humans also have expressive control via vocal chords and bodily poses, which makes emotion expressions multimodal in nature (Rosenthal et al., 1979).
